Suppose you are using a computer to control a RTTY mailbox station that uses telephone lines for control purposes, such as turning the system on and off. One way of writing the software for the computer controller is to have it check the phone line every so often to see if a call is coming in. This would require a software branch to the telephone-checking subroutine as often as possible. This method is called "polling." The hardware that interfaces the computer to the telephone line is polled (examined) every so often to see if a call is coming in. Polling can waste a great deal of time, as well as slow the rest of the program down.

A much better way of doing this is to use interrupts. Every microprocessor has an interrupt input line of some form. If the telephone-interface hardware was connected to the interrupt line on the microprocessor, it would cause an interrupt routine to be executed. An interrupt routine resembles a subroutine. In 6502 assembly language, an interrupt routine might look like this:

```
INT   LDA #00
      STA TURNOFF ;turn transmitter off
      RTI
```

The STA statement stores a zero in a memory location that causes our hypothetical transmitter to shut off. Notice that the interrupt routine ends in an RTI instruction instead of an RTS instruction. This is because an interrupt request causes the status register to be saved on the stack in addition to the program counter. The RTI statement restores both the status register and the program counter to their original states. This way, the main program can resume execution as if nothing happened.

On the 6502 microprocessor, there are two interrupt connections, IRQ and NMI. The IRQ is a *maskable* interrupt, and the NMI is *non-maskable*. A maskable interrupt is an interrupt that can be disabled by setting a special bit in the status register. When this bit is set, the maskable interrupt (IRQ) is ignored. The NMI interrupt is always acted upon; it cannot be masked.

How does the computer know where to branch when an interrupt occurs? In the 6502, there are a number of special locations called interrupt vectors. These locations contain the addresses that the interrupt service routines start at. The vector location for the IRQ interrupt is hex locations FFFE and FFFF; the NMI vector is at FFFA and FFFB.

Next month, we'll explore interrupts further. On some of the newer processors, such as the 8086 and the 68000, interrupts are extremely complex. If one masters the use of microprocessor interrupts, one can design much more efficient computer-controlled devices.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine *by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices,* 73 Magazine, *Pine St., Peterborough NH 03458.*

BUFFALO NY
SEP 7-8

Ham-O-Rama and Computerfest 1984 will be held on Friday and Saturday, September 7-8, 1984, at the Erie County Fairgrounds (Buffalo Raceway, south of Buffalo NY). The hours on Friday are 6:00 pm to 9:00 pm and on Saturday 7:00 am to 5:00 pm. Admission is $4.50. Flea-market vendors' fees are $10.00 for indoor space and $3.00 for outdoor space. Features will include new equipment and video displays, computer demonstrations, technical and nontechnical programs, a chicken barbecue (new this year), and awards. Talk-in on 146.31/.91 (W2EUP/R) and 146.52. For more information, write Nelson Oldfield, 128 Greenway Boulevard, Cheektowaga NY 14225.

LARAMIE WY
SEP 7-9

The Northern Colorado ARC, the University of Wyoming ARC, and the Shy-Wy ARC will jointly sponsor the fifth annual High Plains Ham Roundup on September 7-9, 1984, at the Yellow Pine Campground in the Medicine Bow National Forest (35 miles west of Cheyenne). There are no registration fees except for a modest Forest Service charge for campers. Saturday's schedule will include a campfire cookout and bring-your-own covered-dish extravaganza (barbecued hamburgers and liquid refreshments provided), with sing-along music and entertainment by regional talent. Also on Saturday will be a giant tailgate swapfest, a transmitter hunt, and technical displays. Talk-in on .22/.82 and .25/.85. For further information, write Jack Hayes W7CGK, 1321 E. 22 Street, Cheyenne WY 82001.

UNIONTOWN PA
SEP 8

The Uniontown Amateur Radio Club will hold its 35th annual Gabfest on the Saturday after Labor Day, September 8, 1984, on the club grounds located on the Old Pittsburgh Road, just off Route 51 and the 119 bypass, Uniontown PA. Registration is $3.00 each or 2 for $5.00. There will be free parking, free coffee, and a free swap and shop with registration. Refreshments will be available. Talk-in on 147.645/.045 and 144.57/1.17. For further information, contact UARC Gabfest Committee, c/o John T. Cermak WB3DOD, PO Box 433, Republic PA 15475, or phone (412)-246-2870.

WINDSOR ME
SEP 8

The Augusta Emergency Amateur Radio Unit will sponsor the 1984 ARRL-sanctioned Windsor Hamfest on Saturday, September 8, 1984, at the Windsor Fairgrounds, Windsor ME. The gate donation is still $1.00 and camping will be available on Friday and Saturday nights. Features will include a flea market, programs, speakers, commercial distributors, light meals, and the tradi-

tional Saturday bean and casserole supper. Talk-in on the 146.22/.82 repeater. For further information, contact Don Hanson N1AZH, RFD #2, Box 3678, Greene ME 04236, or phone (207)-946-7557.

MARION IN
SEP 8

The 5th annual Grant County (Indiana) Amateur Radio Club hamfest will be held on Saturday, September 8, 1984, beginning at 8:00 am, at McCarthy Hall, St. Paul's Catholic Church, Marion IN. Donations are $2.00 in advance and $3.00 at the gate. Reservations for an 8-foot table are $2.00 each. Refreshments and free parking will be available. Talk-in on 146.19/.79 and 146.52 simplex. For more information and tickets, send an SASE to Jim Allman WD9EOI, 1108 Spencer Avenue, Marion IN.

MELBOURNE FL
SEP 8-9

The Platinum Coast Amateur Radio Society will hold its 19th annual hamfest and indoor swap-and-shop flea market on September 8-9, 1984, at the Melbourne Auditorium. Admission is $3.00 in advance and $4.00 at the door. Swap tables are $10.00. There will be food and plenty of free parking available, as well as awards, forums, and meetings. Talk-in on .25/.85 and .52/.52. For reservations, tables, and more information, write PCARS, PO Box 1004, Melbourne FL 32901.

SAN ANGELO TX
SEP 8-9

The San Angelo Amateur Radio Club will hold CEN TEX HAMFEST '84 on September 8-9, 1984, in the San Angelo Convention Center. Tickets are $5.00 in advance and $6.00 at the door. Hours for Saturday are noon to 6:00 pm and for Sunday, 8:00 am to 2:00 pm. Special events for the ladies include a Saturday afternoon tour of Fort Concho and Old San Angelo. There will be seminars and group meetings Saturday afternoon and Sunday morning, and a reception for dealers followed by a social hour for amateurs on Saturday night. Talk-in on 146.34/.94. For pre-registration or hotel/motel accommodations, write CEN TEX HAMFEST '84, PO Box 3751, San Angelo TX 76902.

BUTLER PA
SEP 9

The Butler County ARA, Inc., will sponsor their 7th Butler Hamfest on Sunday, September 9, 1984, from 9:00 am to 4:00 pm, at the Butler Farm Show Grounds at Roe Airport, Butler PA. The admission donation is $1.00 and children under 12 will be admitted free. The outside flea market is free and the indoor flea-market vendor's space is $5.00 per 8-foot table. Overnight campers will be welcome and there will be plenty of parking. Other overnight accommodations are available at area motels and fly-in accommodations are available at the airport. Talk-in on .96/.36, .84/.24, and .52. For more information, contact Dan Metrick WA3GDS, 131 Reiger Road, Butler PA 16001, or phone (412)-283-1719.

TORRINGTON CT
SEP 9

The CO Radio Club will hold its hamfest on Sunday, September 9, 1984, from 8:00 am to 4:00 pm, at the Torrington Retirees Drop-in Center, East Albert Street. Admission is $2.00, tables are $7.00, and the fee for tailgating is $5.00. Talk-in on 146.05 and 147.24. For more information, write Donald D. Taylor KA1GKJ, PO Box 455, Watertown CT 06795.

MONETT MO
SEP 9

The Ozarks Amateur Radio Society will hold the 3rd annual Ozarks Amateur Radio Club Congress and Swapfest on Sunday, September 9, 1984, beginning at 11:00 am, at the Monett City Park, junction of highways US 60 and MO 37, Monett MO (between Springfield and Joplin). There is no admission charge and no charge for swap space (available on a first-come, first-serve basis). The buffet dinner begins at 1:00 pm (bring a single covered dish and share in the feast). Talk-in on the 146.37/.97 repeater and 7.250 MHz. For more information, contact the Ozarks Amateur Radio Society, Box 327, Aurora MO 65605.

CARTERVILLE IL
SEP 9

The Shawnee Amateur Radio Association will hold its 28th annual hamfest on September 9, 1984, at the John A. Logan Junior College Campus, Route 13 west, Carterville IL (6 miles east of Carbondale). Admission is $3.00 and flea-market tables are free. Activities will include forums, ladies events, and lunch served on the campus. There will be camping available across the road, motels nearby, and plenty of free parking. Talk-in on 3.925 from 8:00 am to 9:00 am and on 146.25/.85. For more information, phone Bill Johnson W9ERI at (618)-457-7586.

GRAND RAPIDS MI
SEP 15

The Grand Rapids Amateur Radio Association, Inc., will hold its annual Swap and Shop on Saturday, September 15, 1984, beginning at 8:00 am, at the Hudsonville Fairgrounds. There will be dealers, a concession, an indoor sales area, and an outdoor trunk-swap area. Talk-in on 146.16/.76. For more information, write Grand Rapids Amateur Radio Association, Inc., PO Box 1248, Grand Rapids MI 49501.

SEBASTOPOL CA
SEP 15

The Sonoma County Radio Amateurs, Inc., will hold their second annual ham-radio flea market on Saturday, September 15, 1984, from 8:00 am to 2:00 pm, at the Sebastopol Community Center, 390 Morris Street, Sebastopol CA (5 miles west of Santa Rosa, just off Hwy. 12). Admission and parking are free. Tables are $5.00 in advance and $6.00 at the door. Vendor set-up starts at 7:00 am. Features will include a radio clinic, exhibits, refreshments, and an auction around noon. Talk-in on 146.13/.73. For tickets and more information, write SCRA, Box 116, Santa Rosa CA 95404.

MOBILE AL
SEP 15-16

The Mobile Amateur Radio Club will sponsor the Hospitality Hamfest on September 15-16, 1984, beginning at 9:00 am, at the Texas Street Recreation Center off I-10. Admission is free. There will be XYL/YL activities, swap tables, adequate parking, reasonable overnight rates, and good food. Talk-in on 146.22/.82. For more information, contact Porter Chambers KI4FE, 3320 Emelye Drive, Mobile AL 36609, or phone (205)-661-1160.

PEORIA IL
SEP 15-16

The Peoria Area Amateur Radio Club will hold its Peoria Superfest '84 on September 15-16, 1984, at the Exposition Gardens, W. Northmoor Road, Peoria IL. The gate opens at 6:00 am and the Commercial Building at 9:00 am. Admission is $3.00 in advance and $4.00 at the gate; children under 12 will be admitted free. Activities will include amateur-radio and computer displays, a huge flea market, a free bus to Northwoods Mall on Sunday, and a Saturday-night informal get-together at Heritage House Smorgasbord, 8209 N. Mt. Hawley Road, Peoria IL. There are full camping facilities on the grounds. Talk-in on 146.16/.76 (W9UVI). For reservations and more information, send an SASE to Superfest '84, PO Box 3461, Peoria IL 61614.

SUTTON NH
SEP 16

The Connecticut Valley FM Association will hold its 8th annual hamfest and flea market on September 16, 1984, from 9:00 am to 5:00 pm, rain or shine, at King Ridge Ski Area, Sutton NH (exit 11 off I-89). General admission is $2.00 and for dealers or flea marketeers, the fee for tailgating or tables is $3.00 each. Food will be available on the premises and there will be overnight camping only for self-contained units. Talk-in on 146.16/.76 or 146.52 simplex.

MT. CLEMENS MI
SEP 16

The L'Anse Creuse Amateur Radio Club will hold their 12th annual swap and shop on Sunday, September 16, 1984, from 9:00 am to 3:00 pm, at the L'Anse Creuse High School, Mt. Clemens MI. Take I-94 east-bound to the Metropolitan Parkway exit;

then take the Metropolitan Parkway to Crocker; turn left on Crocker to Reimold and then right on Reimold to the last school, L'Anse Creuse High School. Admission is $1.00 in advance and $2.00 at the door. FCC representatives will be there, as well as plenty of new and used gear. There will be lots of food and parking. Talk-in on 147.69/.09 and 148.52. For more information, send an SASE to Maurice Schietecatte N8CEU, 15835 Touraine Court, Mt. Clemens MI 48044, or phone (313)-286-1843.

NEW KENSINGTON PA
SEP 16

The Skyview Radio Society will hold its annual hamfest on Sunday, September 16, 1984, from noon until 4:00 pm, at the club grounds on Turkey Ridge Road, New Kensington PA. Registration fee is $2.00 and vendors' fees are $4.00. Awards will be presented. Talk-in on .04/.64 and .52 simplex.

AUGUSTA GA
SEP 16

The Amateur Radio Club of Augusta will hold its annual hamfest on September 16, 1984, at Julian Smith Casino Park. Tickets are $1.00 each, 6 for $5.00, or 13 for $10.00. Features will include a flea market in the parking lot, a barbecue, refreshments, dealers, entertainment, and on Saturday evening, a hospitality room at Ramada Inn West, Washington Road, rooms 108-110. Talk-in on 145.49 – 600. For more information, send an SASE to D. F. Miller WB4YHT, Hamfest Chairman, 4505 Shawnee Road, Martinez GA 30907, or call 1-(404)-860-3700.

VENICE OH
SEP 16

The forty-seventh annual Cincinnati Hamfest will be held on Sunday, September 16, 1984, at Stricker's Grove, State Route 128, one mile west of Venice (Ross) OH. Admission and registration are $5.00. Features will include a flea market (radio-related products only), exhibits, music, talks, a hidden transmitter hunt, and an air show. Food and refreshments will be available. For more information, contact Lillian Abbott K8CKI, 317 Greenwell Road, Cincinnati OH 45238.

GRAYSLAKE IL
SEP 22-23

The Chicago FM Club will sponsor Radio Expo '84 on Saturday and Sunday, September 22-23, 1984, at the Lake County Fairgrounds, Rtes. 120 and 45, Grayslake IL. Tickets, good for both days, are $3.00 in advance and $4.00 at the gate. The flea market will open at 6:00 am and the exhibits will open at 9:00 am. There will be a giant outdoor flea-market area. Reserved indoor flea-market tables are available for $5.00 per day. Other features will include seminars, technical talks, ladies' programs, and free parking and overnight camping. Talk-in on 146.16/.76. For more information, send an SASE to Radio Expo '84, Box 1532, Evanston IL 60204, or phone (312)-582-6923.

VIRGINIA BEACH VA
SEP 22-23

The 1984 ARRL Roanoke Division Convention and 9th annual Amateur Radio/Computer Fair will be held on Saturday and Sunday, September 22-23, 1984, from 9:00 am to 5:00 pm both days, at the Virginia Beach VA Pavilion. Admission for both days is $4.00 in advance and $5.00 at the door. Flea-market tables are $5.00 for one day and $8.00 for both days. Features include dealers, special displays, forums, computer equipment, a giant flea market, free XYL bingo, and movies for the kids. For tickets and more information, write Jim Harrison N4NV, 1234 Little Bay Avenue, Norfolk VA 23503, or call (804)-587-1695.

WICHITA FALLS TX
SEP 22-23

The annual Wichita Amateur Radio Society Tornado Alley Hamfest will be held on Saturday and Sunday, September 22-23, 1984, at the National Guard Armory, Wichita Falls TX. The hours on Saturday will be 9:00 am to 5:00 pm and on Sunday, 9:00 am to 2:00 pm. Registration will begin at 9:00 am both days and is $4.00 per person in advance and $5.00 at the door. Pre-registration closes Wednesday, September 19th. There will be a large indoor flea market and tables are $3.00 each. Features will include commercial dealers' displays, computer dealers and demonstrations, ladies' activities, and special events. If you wish to take an amateur exam, send FCC form 610 to the hamfest address prior to August 17, 1984. A concession stand will be open both days. Talk-in on 146.34/.94, 147.75/.15, 449.30/444.30, and 449.20/444.20. For more information or pre-registration, contact WARS Hamfest, PO Box 4363, Wichita Falls TX 76308.

DANBURY CT
SEP 23

The Candlewood Amateur Radio Association will hold its annual flea market on Sunday, September 23, 1984, from 10:00 am to 4:00 pm, at the Elks Lodge, 346 Main Street, Danbury CT (exit 5 off I-84). Admission is $2.00 and tables are $7.00. Refreshments will be available. Talk-in on 147.72/.12. For advance table reservations, contact CARA, PO Box 2038, Danbury CT 06810. For more information, phone George Politzi KC2QF at (914)-533-2758, Rose Parrack WA1VOP at (203)-743-6834, or George Slater AF1U at (213)-438-0549.

GAINESVILLE GA
SEP 23

The 11th annual Lanierland ARC Hamfest will be held on September 23, 1984, beginning at 9:00 am, in the Holiday Hall at Holiday Inn, Gainesville GA. There will be free tables and an inside display area for dealers reserving in advance. A large parking lot will be available for the free flea market. Other features will include a left-foot CW contest, a ladies' country store, and many activities. Talk-in on 146.07/.67. For more information and reservations, contact Phil Loveless KC4UC, 3594 Thompson Bend, Gainesville GA 30506, or call (404)-532-9160.

WICHITA KS
SEP 23

The Wichita Hamfest will be held on September 23, 1984, at Camp Hiawatha, 1701 West 51st Street North, Wichita KS 67204. Features will include a flea market, programs, and commercial exhibits. For more information, contact Norm Tramba WAØHWH, 340 S. 1st, Clearwater KS 67026, or phone (316)-584-6425.

WILLIMANTIC CT
SEP 23

The Natchaug Amateur Radio Association will hold its annual giant flea market on Sunday, September 23, 1984, from 9:00 am to 4:00 pm, at the Elks Home, 198 Pleasant Street (off Route 32), Willimantic CT. Admission is $2.00 and children under 16 will be admitted free. Tables are $5.00 in advance and $7.00 at the door (dealers will be admitted at 8:00 am). Food, drinks, and free parking will be available. Talk-in on the 147.30/147.90 repeater and .52 direct. For more information, contact Ed Sadeski KA1HR, 49 Circle Drive, Willimantic CT 06226, or phone (203)-456-7029.

ADRIAN MI
SEP 23

The Adrian Amateur Radio Club will hold its 12th annual hamfest on Sunday, September 23, 1984, at the Lenawee County Fairgrounds, Adrian MI. Because tables are limited, reservations (by check or cash) must be made no later than September 15, 1984. For more information, tickets, or tables, contact Adrian Amateur Radio Club, PO Box 26, Adrian MI 49221.

ELMIRA NY
SEP 29

The Elmira Amateur Radio Association will present the ninth annual Elmira International Hamfest on September 29, 1984, from 6:00 am to 5:00 pm, at the Chemung County Fairgrounds. Activities will include an outdoor flea market, indoor dealer displays of new equipment, and breakfast and lunch served on the premises. Tickets are available at the gate or in advance from Steve Zolkosky, 118 East 8th Street, Elmira Heights NY 14903.

HAMILTON ONT CAN
OCT 6

The Hamilton Amateur Radio Club, Inc., will hold its 2nd annual flea market on Saturday, October 6, 1984, beginning at 8:30 am, at Marritt Hall, Ancaster Fairgrounds, 625 Highway 53 East. Admission is $2.00. Flea-market vendors' 6-foot tables are $4.00 plus admission and commercial vendors' 8-foot tables are $10.00 with admission included. There will be room for 150 vendors and setup will be from 7:00 am to 6:30 am. Coffee, soft drinks, and sandwiches will be available. Talk-in on 146.16/146.76 (VE3NCF). For space reservations, contact HARC Flea-Market Committee, PO Box 253, Hamilton ONT L8N 3C8. For more information, contact Stan VE3GFE on VE3NCF.

WARRINGTON PA
OCT 6-7

The Pack Rats (Mt. Airy VHF ARC) cordially invite all amateurs and their friends to the 8th annual Mid-Atlantic VHF Conference which will be held on Saturday, October 6, 1984, from 9:00 am to 5:00 pm, at the Warrington Motor Lodge, Route 611, Warrington PA, and to their 13th Pack Rat Hamarama on Sunday, October 7, 1984, from 7:00 am to 4:00 pm, rain or shine, at the Bucks County Drive-In Theater, Route 611, Warrington PA. The conference will feature an all-day VHF program, a cocktail hour and get-together at 6:30 pm, and a buffet dinner ($13.00 each) at 7:30 pm. Conference registration is $4.00 in advance (before September 23rd), $5.00 at the door, and includes admission to the Hamarama. Admission to the Hamarama flea market on Sunday is $3.00 and selling spaces are $5.00 each. The gate will open at 6:00 am for sellers (bring your own tables). Food and drink will be available. Talk-in on 146.52 MHz (W3CCX). For more information, contact Hamarama '84, Post Office Box 311, Southampton PA 18966, or phone Lee A. Cohen K3MXM at (215)-635-4942.

BALTIMORE MD
OCT 7

The Columbia Amateur Radio Association will hold its 8th annual hamfest on Sunday, October 7, 1984, from 8:00 am to 3:30 pm, at the Howard County Fairgrounds (15 miles west of Baltimore, just off I-70 on Route 144, 1 mile west of Route 32). Admission is $3.00 and XYLs and children will be admitted free. Tables are $6.00 additional if paid by September 30th and $8.00 additional after that date. Outdoor tailgating is $3.00 additional and indoor tailgating is $6.00 additional. Food will be available. Talk-in on 147.735/.135 and 146.52/.52. For table reservations and more information, write Mike Vore W3CCV, 9098 Lambskin Lane, Columbia MD 21045, or phone (301)-992-4953.

SYRACUSE NY
OCT 13

The Radio Amateurs of Greater Syracuse 1984 Hamfest will he held on Saturday, October 13, 1984, beginning at 9:00 am, at the Art and Home Center Building, New York State Fairgrounds, Syracuse NY (adjacent to Interstate 690, just 3 miles southeast of the NYS Thruway, exit 39, and one mile northwest of Syracuse and Route 81). The hamfest will have complete indoor facilities and, weather permitting, there will be an outdoor flea market in the front courtyard. Volunteer exams will be given for Novice, Technician, and General classes. Breakfast and lunch service will be available. Commercial exhibitors may begin their setup on Friday from 7:30 pm to 10:00 pm and on Saturday from 7:00 am to 9:00 am

DOVER MA
OCT 20

The Middlesex Amateur Radio Club will hold its annual Amateur Flea Market on October 20, 1984, from 9:00 am to 3:00 pm, at Dover Town Hall, Dover MA. Admission is $1.00 and tables are $8.00 each. Refreshments and ample free parking will be available. For further information, send an SASE to Irv Geller KO1N, 1450 Worcester Road, #422A, Framingham MA 01701.

LETTERS

MASS. CLASSES

We're sponsoring Novice and Technician/General classes to be held at Chelsea High School (Chelsea MA) starting September 18, 1984. Classes will be held on Tuesday and Thursday nights from 7:30 to 9:00 pm. The classes are free, but the cost of materials will be paid by the students. For information, contact me at the address below (please include your phone number).

REVIEW

PROPAGATION BY MUFPLOT

If you own an Apple or Commodore computer, MUFPLOT, from Base (2) Systems, 2534 Nebraska Street, Saginaw, Michigan 46601, will make propagation predictions a cinch! Both the Commodore 64 and the Apple II versions were reviewed. They operate in virtually an identical fashion. A VIC-20 version is also available.

Scientists have been making radio-frequency-propagation predictions for years. It used to be a very tedious process that took hours to determine the best frequency between two points. Good math skills and the ability to put a slide rule through its paces were required. With the home computer, it's now possible to let your fingers do the walking!

Since the public became aware of the "Mini-Muf" program created by Bob Rose and his fellow scientists, the market has been flooded with MUF (Maximum Usable Frequency) programs. Some of them are overpriced. Some of them are just poorly conceived. MUFPLOT on the other hand is an excellent example of a good dollar value, delivering a lot of features for the price.

The instructions for MUFPLOT take about 18 small pages. The program is written well enough that many computerists are able to operate it without ever seeing the book!

MUFPLOT will calculate for you the maximum usable frequency, the highest possible frequency (HPF—good for six-meter DXers), or the frequency of optimum traffic (FOT). Additionally, the lowest usable frequency (LUF) is calculated.

Many of the MUF programs on the market do these things. What sets MUFPLOT above many of them are several additions that make the necessary inputs as simple as possible.

When first using the program, it will be necessary to enter your exact latitude and longitude. This information is stored to disk so that MUFPLOT will have the information for all future sessions. The information can be changed easily, should you move or wish to calculate predictions for an area other than you own.

You must enter the end point of the transmission path you wish MUFPLOT to calculate. The beauty of this input is that you can select one of several different methods to specify the location. You may enter the DX prefix, the US postal abbreviation, or a specific latitude and longitude.

You can output the plot adjusted to whatever time zone you wish to use.

Like all MUF programs, you must enter the solar-flux data received from WWV. It's then time to get on with the computations!

Unless you tell it otherwise, MUFPLOT will show the MUF as the upper line on the graph. You may select FOT or HPF and the graph will be changed accordingly.

After just a few seconds, MUFPLOT will begin plotting the graph on the screen. Both the C-64 and Apple II graphics presentations were quite nice. The Apple II version, displayed on an amber monitor screen, was particularly sharp.

If you would like a printed copy of the graph, simply select the print option. You may output as many copies as you like. Standard ASCII characters are used, so the high-resolution graphics presentation is diminished somewhat. This was considered only a very minor trade-off.

As a bonus, MUFPLOT also gives you the correct distance and beam heading from your location to the DX location.

MUFPLOT is supplied on disk. The C-64 version uses compiled Basic (Petspeed) as does the Apple II version. This means faster operation for you. The programs can be backed up, though the C-64 version comes with a "MUFKEY" which must be inserted in the joystick port for proper operation. Failure to do so results in a very interesting "STOLEN" message running across your screen!

If you've been looking for a very versatile MUF program, MUFPLOT may be your answer. It is highly recommended.

A LOOK AT THE ICOM 271A

Two meters. Those two words inspire varied thoughts for different people. To some people, two meters means exciting sporadic-E DX communications, to others, transcontinental Mode-A satellite communications or local SSB chats. Of the many uses for the two-meter band, the most popular is FM-repeater operation. No matter what two meters brings to your mind, one fact is clearly evident: The technology involved in two-meter communications equipment has rapidly advanced during the past few years.

A quick glance to compare an amateur-radio magazine printed a few years ago with a more recent issue is evidence of the incredible advancements that have been made in amateur communications equipment. All areas of amateur communications have changed, from the usual low-band units to the recent computerized RTTY stations. Not overlooked by the jump in technology during the last few years is the ever-popular two-meter radio.

Today, the fully-synthesized two-meter radio with its multitude of memories and other functions is the standard. However, it was not too many years ago that crystallized rigs were the norm. Hand-helds were bulky and offered only five or six channels. Scanning was a rare luxury and rigs that covered the entire two-meter spectrum were often of poor quality. It is difficult to imagine the days when these radios were common, especially for newcomers who glance through the ads in magazines and see the advanced equipment of today.

Rigs with new and innovative features have been coming out repeatedly. Two built-in vfo's, memories, all-mode squelch, digital displays, and even voice synthesizers are examples of the many advancements that have been made in commercial equipment over the past few years. Today's HF rigs include most of these features as standard equipment; however, until recently, a two-meter rig with most of these advanced features incorporated together has been a dream.

Icom's latest introduction to the two-meter world, the Icom 271A, fits the bill of the ideal two-meter rig very nicely. This rig combines most of the features any two-meter operator could ever want. The ideal rig? Perhaps. Read on and see!

Specifications

The unit has many features which make it a joy to operate. The vast majority of operating capabilities are under the direct control of a microprocessor. Two separate vfo's can be used independently or together for either simplex operation or split operation with any desired split. There are 32 memories available; each can store the operating frequency, mode, offset (if any), and a PL™ tone which is generated by an internal PL tone encoder. The encoder is a very handy feature for use with closed repeaters, remote-control applications, etc., and the fact that it's built-in means one less piece of equipment sitting on your shelf!

The front panel of the unit is designed with the user in mind. A good-sized tuning knob and continuous wraparound tuning (which allows tuning off the top end of the band and continuing from the bottom of the band) allow for easy tuning. One of the more enjoyable features of the radio is its two-color luminescent display. It displays all the information needed for logging purposes (operating frequency, offset direction and amount, the vfo in use, the operating mode, receiver incremental tuning degree, memory channel, and PL tone). Of course, not all the information can be displayed at one time! All this is displayed in two colors: red and blue. The unit operates on the standard twelve volts supplied by most power supplies, or an external ac power supply can be purchased as an option. These features, and many more, when utilized to their fullest extent can handle almost any conceivable operating situation.

The IC-271A two-meter transceiver from Icom.

Before we continue with the many features and capabilities of the radio, let's take a look at its design. The radio's physical appearance is very attractive; its sleek gray finish fits in with most other modern radios. Despite its many innovations, the unit has been carefully designed to match other Icom radios as well as most other modern radios in the same class.

Design and Features

The case itself measures 110 mm(H) × 285 mm(W) × 275 mm(D), and the unit weighs 5.2 kg. The Antenna connector, which is the standard 50-Ohm, unbalanced PL-259, is located on the back panel. Also located on the back panel are the Keyer jack, the Ground connection, the External-Speaker jack, the Power-Supply plug, and a removable plate for use with the optional internal power supply. On the left side of the radio are four rubber feet so that it may be stood up on its side. Located on the right side is a handle for easy portability. The bottom has the usual rubber feet and a fold-down stand that lifts the front of the unit an inch or so above the operating surface. The top panel is barren except for vent slits and an enclosure which houses the VOX controls. Now all sides are accounted for except for the one most often seen; the front panel.

At first, the dazzling array of buttons and knobs may be awe inspiring, but as you will soon see, they are arranged by function and are easy to use. In fact, many of the switches are rarely touched after the initial programming of the radio. However, they are there for use whenever an unusual operating condition presents itself.

The first thing that most people notice when they first see the radio is its digital display. The dual colors make for an easy inspection of the current setting of the radio without looking all over at many different switches. Since you have already been introduced to the display, we will leave it for a while then return to it, for it is the central area where current information is displayed.

To the left of the display is the meter. This meter provides a lot of information. It can serve as a signal-strength indicator, a relative-power output meter, and an FM reactance meter. Of course, the mode the radio is in determines what is displayed on the meter. It is back-lighted and is very easy to read in dim light or darkness, and the comparatively large print used on the meter helps.

Between the display and the meter are three LEDs which indicate Transmit mode, Receive mode, and PL tone on. They are easy to see, and each is a different color so they are easily identified in poor lighting conditions where reading the labels would be difficult.

To the left of the meter are six buttons which are used mostly in the programming of the unit's memories. The OW (offset write) button is used to change the frequency of the offset to any desired split, and the + Duplex and − Duplex buttons are used to indicate the direction of the offset. Both the offset and its direction can be stored along with other information in the unit's 32 memories.

Located in the same group of six buttons are the PL tone select switches, which again are used mostly during the programming of the memories. The Tone button turns on the internal encoder so that the indicated tone will be transmitted. The Select button is used to choose one of the 32 available tones, which can be stored along with the other information in the memories.

Finally, the last of these six buttons is he Check switch. It is similar to the Reverse button on many other two-meter radios in that it allows you to change the receive frequency by increasing or decreasing it by the offset stored with the frequency. Using this feature, you could check the input of a repeater to see if you could hear the other party without the aid of the repeater, and thus determine if simplex operation is possible. The check feature is activated only as long as the button is depressed.

The lower left corner of the front panel contains the greatest number of buttons and knobs. The Power switch, a push-in locking switch, is located in the middle of the row of switches at the far left. Directly below the Power switch is the Transmit/Receive switch. It is the usual lever switch and is used mostly on CW. The microphone connector is the next in line and is an 8-pin connector with the capability for remote up/down frequency control. The Mode buttons are located to the right of the Power and T/R switches.

The modes available are (from top to bottom): FM, USB, LSB, and CW. These are not locking switches, and when they are pressed, the mode indicator in the display switches to the correct mode, and when released, the switch returns to its original position. Next to the Mode buttons are several function buttons. These switches lock and must be pressed again to return them to their normal state. They are (from left to right): VOX, NB (noise blanker), AGC (automatic gain control), Meter, Preamp, and Mode Scan.

The VOX is simple enough; press it in when you want the transmitter to trip whenever there is a signal loud enough to trip the threshold control which is located under a panel on the top of the radio. However, the VOX only works in the SSB and the CW modes, not in the FM position.

The noise blanker is easy to use also. Whenever there is any interference coming into the radio, push the button in. It will attenuate electrical pulse noise from the power line and the air; however, it is fixed and not variable.

The Meter switch is used for switching between the two functions of the meter when in the Receive mode. It is a relative-power indicator when in the Transmit mode. However, it can serve as either an S-meter or an FM reactance meter depending on which position the switch is in.

The Preamp switch kicks in the optional preamp when it is needed. However, without the preamp installed, the switch does nothing no matter which position it is in. In short, the switch is useless until the optional preamp is installed.

The last of the function switches is the Mode Scan. It is used when you want to scan memories that contain only a selected mode. For example, it could be set to FM and scan only only those memories which contained FM as their mode. Such a feature could be used for selectively scanning the local repeaters or for the satellite beacons, etc.

Three knobs and the Phones jack are located below the function switches. The Phones jack is the standard 0.25-inch phono-plug jack. The knobs each contain concentric dials and thus each serve a dual purpose.

The first concentric knob moving from left to right is the AF/RF Gain. It, of course, is used to set the volume of the audio and the level of the rf gain. Next in line is the Squelch/Tone knob. By turning these, you can set the all-mode squelch so that no sound will be heard unless there is a signal present on the frequency. Also, the tone of the audio can be adjusted. The last knob on this row is the Mic Gain/RF Power. The Mic Gain is used to set the drive from the microphone necessary to modulate the output signal, and the RF Power is used in conjunction with the relative-power output meter to adjust the power output up to 25 Watts.

Located beneath the digital display and to the right of the function switches are the main tuning knob and a few other buttons. The tuning knob is very civilized and responds well. It's weighted perfectly and rotates effortlessly. To the lower left of the tuning knob is a small square switch. It is used to lock the display in order to prevent accidental frequency change from bumping the tuning knob or inadvertently pressing a button. It is also used in conjunction with the optional internal speech synthesizer when it is installed.

To the right of the tuning knob are three switches (from top to bottom): TS (tuning step), DFS (dial function select), and Split. The first, tuning step, is used to change the tuning increment to 1 kHz in any mode. The 100-Hz digit on the display is cleared to show 0. The tuning returns to normal increments when the switch is released. This function allows quick QSYing over a great frequency range in SSB and CW and tuning to FM signals which are not located on the standard 5-kHz step.

The next switch in line, the dial function select, serves two purposes, depending on whether you are in memory mode or using the vfo. If you are tuning with the vfo, the switch allows you to lock the vfo and use the tuning knob to rotate through the 32 memories. If you are recalling memories, activating the switch will cause the memory-channel select to lock; the tuning knob now serves to adjust the frequency.

The last switch is the Split switch. It is used to allow the unit to operate at any conceivable split. By activating the switch, one vfo is used for the transmit frequency and the other is used for the receive frequency. Whichever vfo was in use when the switch was pressed will become the receive frequency.

To the right of the tuning-knob area are another knob and a few more switches. The knob is the RIT. The RIT is used to adjust the receive frequency by up to 9.9 kHz in either direction. This is very useful for sensitive fine tuning where you do not want to disturb the transmit frequency knob. The knob is activated by pressing the RIT button, and the RIT is cleared by pressing the Clear button.

Below the RIT controls are MHz Up and Down switches. Because the two-meter band is so large, tuning up and down the band with the tuning knob would take quite a while, not to mention how tiring it would be! To prevent this problem, the MHz Up and Down switches were added. You can jump up or down in 1-MHz steps with a press of the appropriate switch.

The last group of switches in the front panel is located to the right of the display and above the RIT controls. These six switches control the operation of the vfo and the memories. The A/B switch is used to switch between vfo's A and B. The A = B switch is used to set the two vfo's to the same frequencies. The VFO/M switch is used to switch between the vfo mode and the memory mode. In the vfo mode, the tuning knob is used to change the frequency of the vfo. However, in the memory mode, the tuning knob is used to select one of the 32 memories. The Write switch is used to write all the information indicated on the display into the memory. The M-VFO switch is used to put the contents of a memory into a vfo, and the Scan switch is used to either scan through the memories, or to scan through a selected range of frequencies within the limits determined by the contents of the first two memories.

Now that you are well aware of the many features of this radio and how they work, we can look at how they are applied in typical operating situations. The number of buttons and switches may seem imposing at first, but they are easy to learn and even easier to use. All these features may seem a bit much, but as you will see, they can be utilized effectively to increase your operating pleasure in all but the most simple situations.

When I first received the radio, it took me about 10 minutes to set it up and attach it to my TS-130 power supply. After playing with it for a few minutes I decided it was time to break out the manual and put it through its paces. After tuning around and punching the buttons, I learned that not using the memories takes away a lot of the radio's capabilities, so I tried to program one.

Memories

The manual gives clear examples of how to program the memories and after the first one was programmed, the manual was no longer needed. Reserving the first two memories for the upper and lower frequencies for the band-scan feature, I decided to put a local repeater into the third memory. First I set the mode to FM and tuned the vfo to 145.23 MHz, which is the output frequency of the repeater. Then I set the offset to 600 Hz by pressing the offset write button and turning the tuning knob until 600 was displayed. Next I pressed the −Duplex button to register the offset as negative, and I was done. However, if the repeater had required a PL tone for access, I could have entered it also by pressing the Tone Select button and turning the tuning knob until the desired tone was displayed.

In order to store the specifications I had just set into memory three, I put the radio in the memory mode by pressing the VFO/M button and turning the tuning knob until memory 03 was displayed on the right side of the display. Next, I double-checked the display to make sure the information was entered correctly. Yes, the display indicated the correct frequency, offset, mode, and memory, so I pressed the Write button and the information was entered in memory 3. The same procedure was repeated for the other repeaters I wanted to enter into memory, changing only the frequency, offset direction, etc., depending on how different this repeater was from the one I'd just entered. By canceling out the offset, simplex frequencies can be entered along with their modes, i.e., 146.52 FM, 144.30 CW, 144.85 SSB, etc.

Now that there were several frequencies stored in the memories, I was able to recall them by putting the radio in memory mode and turning the tuning knob. As each memory was displayed, the information was automatically entered to the display and the radio was ready to operate as set in that memory. By pressing the Scan button in the memory mode, the radio scans through the 32 memories and stops whenever a signal interrupts the squelch. After a few seconds, it continues scanning. Pressing the Scan button again will stop the scanning.

To put the contents of a memory into a vfo, I recalled the memory in the memory mode, then pressed the VFO/M button again to enter the vfo mode. By pressing the M-VFO button, the memory contents were entered into the indicated vfo. Now I was able to take advantage of the vfo while retaining the desired memory specifications.

Operating the Radio

As you can well imagine, all of these features along with the memories can make operating two meters a lot of fun. The versatility of the rig and its ability to adapt to different operating habits ideally suits this radio to any two-meter user. I have used the rig under many different operating conditions and have always been pleased with its performance.

I was able to put the radio through a test during the VHF sweepstakes and it performed beautifully. I ran it at a full 25 Watts into a 10-element yagi mounted in the attic and had some surprising results. My most distant contact was Connecticut from my home near Philadelphia, Pennsylvania. This was very good considering the number of people that were calling him also. I found the noise blanker to be a useful feature and my audio reports on SSB and FM were excellent. I tried to utilize every feature during the contest and found them all to be a great help.

The radio's precise tuning and the RIT feature make it excellent for satellite use. Although I received the radio too late for use in the recent space shuttle mission, I am sure its features would have been a great help. The quick access to the memories would have been a great boost in monitoring all the transmit and receive frequencies.

The radio performs just as well under more conventional operating conditions such as rag-chewing, repeaters, and nets. Because the memories may be set up in any manner, the radio may be customized to any user's typical operating conditions. The more exotic features such as the unlimited splits are there when you need them and are not hard to use. My radio has been operated on all modes from CW to RTTY (AFSK) and is testament to the great versatility of the rig. This is the super rig that every two-meter buff has dreamed of. And, if the built-in features are not enough, there is a wide array of options available.

Options

Among the options available, the internal power supply and speech synthesizer have already been mentioned. Other options include a PL tone decoder and a computer interface. Of course, the usual array of microphones and other accessories is available. The radio comes equipped with an up/down mike, but it lacks touchtones™, so the touchtone mike is one of the first accessories you should look at. Also, a more powerful version of the 271A is available, the IC-271H, which has an output power of up to 100 Watts. A version is also available for the 440-MHz band, the IC-471.

Conclusion

Overall, I was very pleased with the

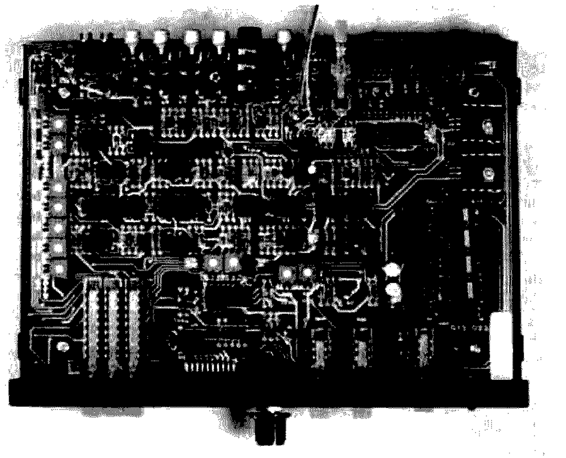
Send your thoughts to Review Editor, *73: Amateur Radio's Technical Journal*, Peterborough NH 03458.

AEA's CP-1 Computer Patch.



Interior view.

radio, both in its design and operating abilities. It is definitely a first-class rig which is sure to be a big success. I got the last one the store had in stock! If Icom is listening, a VOX for FM would be nice. It is available for hand-helds and should be included in this excellent rig. I have just about run out of words of praise for this stupendous transceiver. Let it suffice to say that this rig would top my list of necessary equipment for two-meter operation.

For further details, contact *Icom America, Inc., 2112 116th Ave. NE, Bellevue, WA 98004; (206)-454-8155.* Reader Service number 486.

THE AEA CP-1 COMPUTER PATCH

Many amateurs have joined the computer revolution in the past few years. The availability of inexpensive microcomputers has resulted in the appearance of approximately 100,000 of these units in ham shacks around the world.

As it comes, the home computer lends itself well to logging chores, dupe checking, and propagation prediction. All of these applications require software only. To realize the full potential of a computer in the ham shack, one or more hardware interfaces is required to safely interface the micro to the amateur-radio equipment.

Some of the most popular applications for a computer include sending and receiving RTTY, AMTOR, ASCII, and even CW. Numerous software packages are available to teach your computer how to speak these "foreign" languages. The best software in the world is nearly useless if the incoming signal does not accurately convey the received data.

The AEA people have designed the CP-1 Computer Patch to match virtually all makes and models of amateur transceivers and separates to most home computers. It does its job extremely well. AEA has been making code and RTTY readers for some time. The CP-1 is a logical extension of the technology developed in these units.

One of the first things you notice when you take the CP-1 out of the box is its relatively small size. The old vision of everything having to do with RTTY being big and bulky is finally dying. The style is very clean and makes a pleasing addition to the ham shack.

An exploration of the inside of the CP-1 reveals superior construction techniques. The circuit board has the look and craftsmanship of the highest-quality commercial gear.

Connection of the CP-1 is relatively simple. The detailed and easy-to-read instruction manual makes the task painless. A connection from the audio output of your rig is needed for reception. A cord from the CP-1 to the microphone jack of your radio will also be needed if you wish to transmit.

An external power adapter is provided with the CP-1. Often this is an extra-cost item with other interfaces.

With the CP-1 connected and some software loaded in your computer, you are ready to go! The controls on the front panel of the interface are straightforward.

After turning the power on, you need to select the shift you wish to use. Three push-buttons allow selection of a narrow bandwidth for CW reception, or a 170-Hz bandwidth for standard RTTY reception. In addition, a variable shift position allows reception of virtually any nonstandard shift up to 1000 Hz.

The center frequency of the bandpass filters in the CP-1 is also changed depending on your selection of CW or RTTY reception. In the CW mode, the filters are centered around 750 Hz, the frequency most CW filters in transceivers are tuned to. For RTTY, the center frequency is shifted up above 2125 Hz to accommodate standard RTTY audio frequencies.

Though the CP-1 will receive almost any shift, it is designed to transmit only 170-Hz tones. A simple modification outlined in the instruction manual will allow 850-Hz transmission if you need it for MARS or other work.

How well does it work? In side-by-side comparisons on regular amateur transmissions, the CP-1 often provides the best reception of even very weak signals. There are several notable things about the CP-1's performance.

Adjacent signal rejection is superb! Many computer interfaces fall a bit short in this category, but the CP-1 compares favorably to sophisticated terminal units. It is possible to tune to even a weak signal with a very strong signal nearby and realize virtually 100-percent copy.

An indication of the clean signal coming from the CP-1 is highlighted when tuning between signals, or when the frequency is idle with only background noise present. Many interfaces will try to interpret the random noise and signals as real data. The CP-1 provides a "quiet" output under most conditions, keeping the computer screen clear until a signal is properly tuned.

The tuning indicator provided on the CP-1 does a good job, performing almost as well as a tuning scope. For the purist, scope outputs are provided on the back of the unit.

No problems were encountered using the unit on transmit. Provisions are made to match the level and keying requirements of most equipment.

I tested the CP-1 with MBATEXT, AEA's software package, HAMTEXT and HAMSOFT from Kantronics, and numerous programs of my own design. It performed well with all of them.

If you are interested in copying commercial transmissions, the variable shift feature is a must. Most transmissions outside of the amateur bands occur at 425- or 850-Hz shift. The CP-1 adequately provides reception at these shifts. Adjustment of the variable shift control requires some learning, but the instruction manual provides the instructions you need to properly tune the CP-1 in this mode.

The AEA CP-1 has a suggested list price of $239, though it is currently being offered by many dealers at a much lower cost. Additionally, the CP-1 is sold in packages with AEA software at an even greater savings for the packages.

If you are looking for an excellent dollar value in a computer patch, the CP-1 is hard to beat. It is highly recommended.

DX-1 PROPAGATION SOFTWARE FOR THE APPLE

Knowing when and where to listen for DX is half the battle in logging a new country or prefix. If you own one of the Apple II series of computers, the DX-1 program from DX Enterprises, 5861 Bridle Way, San Jose, California 95123, can provide you with very detailed propagation information.

DX-1 is much more than just an implementation of the popular maximum usable frequency program. It provides at least one feature that no other propagation program that I have seen includes.

For those of you who are interested in the programming aspects of computing, you may find it interesting that DX-1 is written using the Pascal language. Virtually all of the other propagation programs are written in some version of Basic. Pascal is a structured language that its proponents feel allows programming in a very logical fashion. No program line numbers are used.

The DX-1 package takes a machine with 64K of memory and one disk drive. Loading the package takes something just under four minutes. The long load time occurs because the Pascal language must first be loaded in, and then information on more than 400 unique radio locations is absorbed by the computer.

Operating the program is made easier by reading the manual as you input the requested information. Numerous examples are contained in the twenty-page book that accompanies DX-1.

Rear-panel view.

You will need to know your latitude and longitude. Unlike similar programs, DX-1 does not store this information anywhere for you. This was considered a minor inconvenience.

Selecting the target area is quite easy. You may input coordinates for a specific location, or you may use the information contained in DX-1 to search by country. It's not even necessary to know exactly how to spell the target area. For example, Sri Lanka was found by asking DX-1 to search for SRI. If the computer is unable to outguess you, backward and forward scrolling through the list will locate the country you have in mind.

As soon as you input your location and the date, the program calculates sunrise and sunset for your location. Be careful! The times given are in GMT (or UTC if you prefer) *not* local time! A similar calculation is made on the target area.

As with all MUF programs, you will need the 10.7cm solar-flux reading. DX-1 also requires the geomagnetic "A" index. Both are available at 18 minutes past the hour from WWV. The additional use of the A index and other calculations allow DX-1 to calculate a "quality" factor for the path.

After inputting the information, it's time to sit back and wait about half a minute for DX-1 to do its thing. The information is displayed on the screen in table form. If desired, the screen information can be sent to your printer for a more permanent record.

DX-1 will also calculate the frequency of optimum transmission (FOT) when requested. This, too, can be sent to the printer.

Additional "nice-to-have" information, such as beam headings for short and long paths, distances for both, and the prefix for the target area, is displayed.

The area in which DX-1 shines, if you will pardon the pun, is in greyline calculations. Old-time DXers and SWLs know that enhanced conditions exist between two points when both are undergoing sunrise or sunset at the same time. DX-1 will tell you what to look for during these conditions on any given day.

Even the width of the greyline area can be specified. Normally a 15-degree width is adequate. Since there are 24 hours in a day and a circle has 360 degrees, the 15-degree width corresponds to a one-hour window, or 1/24th of a day.

Greyline calculations are complex and time consuming. It takes about five minutes for DX-1 to do the job. When selecting greyline calculations you must specify whether you want the output to go to the screen or to the printer. You cannot go back later and print what you saw on the screen without DX-1 going through all of the calculations again.

The programmers of DX-1 deserve some applause for taking the time to format the printout of the greyline calculations. A form feed is issued so nothing is typed on the perforations. The headings are also duplicated at the top of each page. A nice touch!

DX-1 was judged to be of great value to the serious DXer. Some of the times involved in loading and calculating suggest that DX-1 might be better suited to everyday operations rather than a contest situation where you might be using your computer for other things, like logging for example, at the same time.

The absence of a graph-type display of the MUF and FOT is a minor flaw in DX-1. The information provided in table form is of course just as accurate, perhaps even more so.

If your interests are a bit more routine, a somewhat more compact version, minus the greyline-calculation option, is available. It is called DX-2 and was not reviewed.

Take a byte out of propagation prediction! DX-1 for your Apple computer will help do the job.

NEW PRODUCTS

PACKET RADIO CONTROLLER FROM AEA

Advanced Electronic Applications, Inc., has announced the introduction of the Model PKT-1 packet radio controller through an arrangement with Tucson Amateur Packet Radio, Inc. (TAPR), Tucson, Arizona. AEA started delivery of the PKT-1 to its dealers in June.

The PKT-1 is a packaged and warranted version of the well-known TAPR do-it-yourself kit board with version 3.1 software, and includes application assistance and a year's conditional warranty. More than 1000 users of the TAPR kit board now exist throughout the world.

Packet radio is a burst mode of data or text transmission utilizing AFSK, FSK, or PSK modulation. On VHF it runs at 1200 baud typically, and uses CRC error checking, ensuring an extremely low error rate. Multiple users may share a simplex or duplex channel simultaneously on a time-share multiplexed basis.

Any packet station using the PKT-1 may operate as a store-and-forward repeater (digipeater) for someone else's transmission while concurrently functioning as a regular packet station. Up to 8 digipeating stations may be used between two terminal stations. Digipeating allows routing the transmission path around physical obstacles blocking a line-of-sight radio path and allows extending the link beyond line-of-sight distances.

For more information, contact your closest AEA dealer, or *AEA, PO Box C2160, Building O&P, 2006-196th SW, Lynnwood WA 98036-0918; (216)-775-7373.*

AMTOR CONVERTER FROM INFO-TECH

The new Info-Tech M-44 AMTOR converter allows most RTTY terminals to be used on the recently-approved AMTOR RTTY mode. Interface to the terminal is via serial TTL or RS-232 levels, and either ASCII or Baudot terminals may be used.

The unit also features a built-in modulator and demodulator with pre-filter, full-time ATC, and two transmit buffers. All control of the M-44 and transceiver is by simple commands entered via the terminal keyboard.

This converter is American designed and manufactured and will operate in the ARQ, FEC, and ARQ-monitor modes.

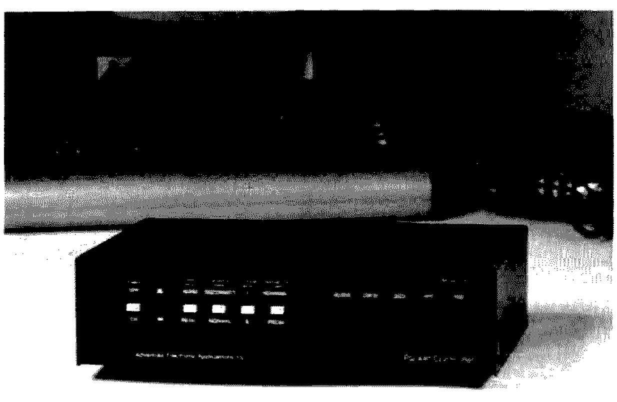
For more information, contact *Digital Electronic Systems, 1633 Wisteria Court, Englewood FL 33533.* Reader Service number 478.

REGENCY ELECTRONICS 20-CHANNEL SCANNER

Regency Electronics, Inc., now offers a 20-channel programmable scanner with complete, continuous coverage from 25 to 550 MHz. This receiver has microprocessor control for direct keyboard entry of frequencies. The Regency MX-5000 is available at participating Regency Electronics dealers.

The MX-5000 scans two to twenty channels automatically, or channels may be selected manually. Its wide coverage includes high and low VHF, UHF, and UHF "T" for police, fire, emergency services, business band, marine radio, radio-telephone, and National Weather Service broadcasts. It covers VHF aircraft, five amateur-radio bands, and TV audio and

Info-Tech's M-44 AMTOR converter.



The PKT-1 packet radio controller from Advanced Electronic Applications.

The Regency Electronics' 20-channel scanner.

FM broadcast. Any frequency can be selected directly at the keypad; each keypress is verified by a beep. A memory-backup system saves frequencies in memory even if power is disconnected, yet no battery is required.

Any frequency can be programmed into priority channel one and sampled at approximately two-second intervals; if active, it automatically overrides any other signal. Any selected channel or channels can be "locked out" and omitted temporarily from the scan. A scan-delay feature can be invoked to avoid missing callbacks; this feature delays resumption of scanning for approximately two seconds after a transmission ends. A choice of two scan speeds samples channels as rapidly as five per second or at a slower rate.

The MX-5000's search feature helps locate unknown or "hidden" channels within any specified frequency range; it searches for active channels in (selectable) 5-, 12.5-, or 25-kHz increments; the mode of reception (AM, wideband or narrowband FM) is also selectable. When a signal is received, its frequency is displayed on the digital readout. Search may then be resumed, or the new frequency stored in one of the 20 scan channels.

The multi-function digital display shows both channel number and frequency (plus MHz or kHz) when scanning (just frequency while searching, plus the receive mode and search frequency increment), and whether the priority mode has been selected or if the displayed channel has been locked out. Error messages are displayed in the event of invalid keyboard entries. A built-in 24-hour digital clock offers the time whenever the MX-5000 is plugged in. The display is side-lighted for easy nighttime legibility.

A slanted front panel offers easy visibility and operation. A keyboard lock switch can disable the keyboard to prevent inadvertent entries. Dual-concentric volume and sqelch controls help tailor the audio delivered to the built-in speaker or external speaker jack. An external antenna jack allows the addition of a full-size antenna for improved reception; an attenuator switch (−10 dB) helps prevent overload from strong local stations in highly congested signal areas.

The MX-5000 comes with a telescoping antenna, wall-mounted ac power supply, a 12-V-dc power cord for use in a car or other vehicle (where not prohibited by law), and mobile-mounting bracket. It measures 5.4"W × 3.1"H × 7.9"D(138 × 80 × 200 mm).

For additional information, contact *Regency Electronics, Inc., 7707 Records St., Indianapolis IN 46226-9989; (317)-545-4281.* Reader Service number 483.

TRAINING TAPES FOR CODE AND THEORY

Radio School, Inc., founded by Gordon West WB6NOA, is offering a large selection of code and theory training tapes to the amateur-radio community. Gordon West has also produced technical tapes dealing with antennas, grounding techniques, and maritime-mobile installation.

Over 700 free volunteer-examiner tape sets were mailed recently to instructors throughout the country, containing FCC-type volunteer-examiner code tests at 5-, 10-, 13-, and 20-word-per-minute levels. There were ten different versions of each tape to prevent students from memorizing them.

Radio School offers over 30 individual one and one-half hour long code cassette speed-building courses. There are also over 20 individual tapes covering theory examination preparation, and 10 tapes dealing with amateur radio equipment installation techniques.

The tape courses are in stereo; students can listen to both channels in the car, but separate the voice channel out when listening to code practice at home with a pencil. Any tape player with a balance control can easily fade out the voice channel. When played on a mono tape recorder, the student will hear both channels.

Radio School was first to offer complete 4-cassette theory courses covering the new FCC questions from Novice to Extra. These theory courses also feature live sounds of amateur radio operating to assist the student in recognizing some of the topics discussed on the tape.

The Gordon West Radio School tapes are available directly from the School. For a catalog or more information, contact *Radio School, 2414 College Drive, Costa Mesa CA 92626.* Reader Service number 477.

THE DAVLE TECH DESOLDERING STATION

The model SA-4 desoldering station from Davle Tech, Inc., features a self-contained high-volume vacuum pump for easy removal of solder from through-hole and multi-layer applications. Additional features include trigger-actuated pistol-grip design, "no-clog" system with transparent solder collector, and easy collector cleaning; grounded for use with delicate MOS and CMOS components, it has a low-maintenance design and a specially-processed long-life nozzle.

The SA-4 is available for either 115-V or 230-V 50/60-Hz input, and is compact and lightweight for portability. A handy tool holder is built into the control unit. Includes .039"(1.0 mm) nozzle. Optional nozzles available from .031"(0.8 mm) to .063"(1.6 mm) diameter.

For more information, contact *Davle Tech Inc., 2-05 Banta Place, Fair Lawn NJ 07410; (201)-796-1720.* Reader Service number 481.

THE VOICE PAK FROM SPECTRUM PROJECTS

Spectrum Projects has introduced a CoCo voice synthesizer, the Voice Pak, that uses the Votrax SC01 synthesizer chip in a cartridge-style pak. It provides an unlimited vocabulary with automatic or user-supplied inflection, a variable voice-level adjustment, plus four programmable levels of pitch. With a single line of code, the Voice Pak adds speech to any Basic program in minutes.

The system comes complete with a user instruction manual, software cassette with demo programs, text-to-speech scanner, and a "Word Manager" that constructs custom user dictionaries. The unit is fully assembled, tested, and ready to plug in and talk. The Voice Pak allows any prompting application in education, speech therapy, games, robotics, or security.

For more information, contact *Spectrum Projects, 93-15 86th Drive, Woodhaven NY 11421; (212)-441-2807.* Reader Service number 482.

ICOM'S MULTIMODE BASE-STATION TRANSCEIVER

Icom announces the IC-471H 430–450-MHz transceiver with 75-Watt transmitter, low-noise PLL circuitry, and high-sensitivity receiver.

Standard features include 75 Watts rf output, FM, SSB, CW modes, 32 full-function tunable memories (storing frequency, offset, offset direction, and tones), 10-Hz tuning increments, 1-MHz up/down buttons, scanning of memories, memory modes, or band, all-mode squelch, and dual vtos. Its size is 4-1/2" (H) × 11-1/2" (W) × 13-1/4" (D).

The IC-471H uses 12-V-dc power and may be supplied from an external source (IC-PS15 or IC-PS30, optional) or from an optional internal ac power supply (IC-PS35). Other optional features include an IC-AG35 switchable mast-mounted preamplifier, UT15S encoder/decoder (PL encoder is standard), IC-CT10 computer interface, IC-EX309 computer-interface connector, and IC-EX310 voice synthesizer.

For more information, contact *Icom America, Inc., 2112 116th Avenue NE, Bellevue WA 98004, (206)-454-8155.* Reader Service number 476.

BV ENGINEERING'S FIRST SOFTWARE

BV Engineering has announced the first three products in what will be an entire line of professional software sharing common data files.

ACNAP is an ac network-analysis program that analyzes electronic circuits consisting of resistors, capacitors, inductors, and active components such as transistors and operational amplifiers. ACNAP will work with component tolerances to perform Monte-Carlo, Sensitivity, and Worst-Case analyses.

PLOTPRO is a general-purpose scientific graph-printing program which makes linear/log/semi-log graphs on any 80- or 132-column printer. PLOTPRO supports vertical and horizontal formats, two Y axes, multiple plots, auto-scaling, labeling, and grid lines.

SPP is a general-purpose signal-processing program that analyzes linear and nonlinear systems in the frequency domain and in the time domain. SPP supports FFT and inverse FFT, LaPlace transforms, transient analysis, and a complete set of signal generation and manipulation routines. All programs available for CP/M, MSDOS, PCDOS, and TRSDOS.

For a free flyer and further information, contact *BV Engineering, Box 3429, Riverside CA 92519; (714)-781-0252.* Reader Service number 480.

CMC COMMUNICATIONS VOICE-OPERATED SQELCH

CMC Communications is offering a voice-operated squelch on a small circuit board for mounting inside most HF/SSB transceivers and receivers. The VOS requires that different and select components of the voice spectrum be present at the same time to operate. It ignores heterodynes, the Russian woodpecker, and noise regardless of level, yet it is extremely sensitive to weak signals when the human voice is present. All adjustments are made at the factory and a remote on/off switch is provided. Simple connections are made to the speaker leads and 9 or 12 V dc. This product is used extensively worldwide in commercial marine, land, and military systems.

For further information, contact *CMC Communications, Inc., 5479 Jetport Industrial Blvd., Tampa FL 33614; (813)-885-3996.* Reader Service number 479.

BAKER AND HOWLAND: ANOTHER NEW ONE

Another new country will soon be added to the ARRL DXCC Countries List: Baker and Howland Islands, located in the middle of the Pacific Ocean. Let's look at the process whereby new countries are added to the DXCC list by following the saga of the latest country on that list.

As with many "new ones" in modern DX history, the new country of Baker and Howland Islands rises out of the ashes of a former DXCC country which will be deleted from the DXCC roles when Baker and Howland is added. The old DXCC country of Baker, Howland, and the American Phoenix Islands will no longer exist, and future contacts with amateurs in that region will count for other DXCC countries.

The Baker-Howland story begins in the 19th century when Great Britain claimed the Line Islands and the Phoenix group. These are widely-separated, small coral atolls near the equator, south and southwest of Hawaii. The total land area in this region is less than 20 square miles. The atolls were known primarily for their extensive bird populations, which produced what was the chief export of the islands in the 19th century, bird guano.

Great Britain was not the only country to take an interest in these islands. The United States claimed the islands by right of discovery, and even issued some mining permits to guano collectors. From 1937 on, some US personnel lived permanently on Canton, an island in the Phoenix group.

In 1939, Great Britain and the United States sat down to resolve their differences in this area. Neither country was willing to give up its claim to the islands of the region, so a compromise was reached whereby *both* countries would administer the birds and their nests. This joint administration recognized the claims of both countries. Since the bottom had fallen out of the guano market, no one seemed particularly interested in the area.

Our little disagreement with Japan (i.e., WWII) changed that, and the US built and maintained a major military base on the largest island of the region (and the largest coral atoll in the world), Christmas Island. The joint administration of some of the islands in the Phoenix group continued until 1970, when the US Air Force took over control of Canton Island (where it had a military base). But the agreement with the British continued.

So matters stood until 1979, when the Republic of Kiribati was born. Kiribati stretches several thousand miles across the central Pacific from the Gilbert Islands in the West to the Line Islands far to the east. With this change, the British relinquished their claim to the islands in the area and gave their portion of control to the new Kiribati Republic.

Meanwhile, the joint administration of Canton Island in the heart of the Phoenix group created an interesting amateur-radio situation. A ham station on Canton could operate under US rules with a KH1 callsign (formerly KB6 before the FCC started messing around with callsigns), or that same station, in the same location, could operate under British control with a VR1 call.

There are very few spots in the world which count for more than one DXCC country at one time. (A Peace Park on the border between Norway and Sweden is the only other which comes to mind. Anyone know of any others?) A ham on Canton could hand out a DXCC contact for the British Phoenix Islands, and then, by switching calls, could hand out a QSO good for the American Phoenix DXCC credit.

The independence of the Kiribati Republic didn't change the basic nature of this amateur-radio anomaly; only the callsigns changed. The Kiribati Republic began issuing T3 calls, including T31 calls for the Central Kiribati Republic (the Phoenix Island group). Contacts from Canton Island could still count for either the American Phoenix DXCC credit or for Central Kiribati T31.

Eric Sjoland SM0AGD operated from Canton a couple of years ago and helped knock both KH1 and T31 off the Most Wanted List. Eric operated under his KH1 call one day, and then switched over to his T31 call the next.

Meanwhile, even while Eric was making thousands of DX QSOs from Canton, the Northern California DX Foundation was laying the groundwork for a new DXCC country.

Soon after the Kiribati Republic was created, the United States signed a Treaty Of Friendship with the new country. In this treaty, the US renounced its claim to the islands in the Phoenix group, including Canton. The Air Force had decided that it no longer needed its Canton base, and therefore closed the base at about the same time.

The workings of the US government are slow, and it was almost four years before this treaty was ratified by the Senate. Once President Reagan signs the treaty, the US no longer has any territorial claim to the islands and loses the right to issue amateur-radio licenses for the region.

The amateur-radio implications of the treaty go beyond callsigns. The US is retaining its claim to the tiny islands of Baker and Howland, just north of the central Kiribati Islands. These two islands were never under joint administration, nor were they part of the Republic of Kiribati.

But the DXCC country is defined as Baker, Howland, and the American Phoenix Islands, including Canton. When the treaty is signed, Canton (and the other American Phoenix Islands) will no longer be under US jurisdiction. So the majority of the present DXCC country will vanish.

Members of the Northern California DX Foundation recognized that the old DXCC country could not continue unchanged. As they saw the situation, the old country of Baker, Howland, and the American Phoenix Islands should have been deleted from the DXCC list when the American Phoenix Islands reverted to sole ownership by the Kiribati Republic. Further, the islands of Baker and Howland, now cast off from the larger, populated Phoenix Islands, were a prime candidate to become a new DXCC country.

The NCDXF carefully assembled the documents detailing the administrative changes in the region and submitted a request to the ARRL DX Advisory Committee to delete the old DXCC country of Baker, Howland, and American Phoenix and add a new country of Baker and Howland Islands.

The carefully-reasoned and well-written submission to the DX Advisory Committee argued that with the loss of the American Phoenix Islands from the old DXCC country, that country should cease to exist. To support their request, the NCDXF cited several precedents in DXCC history in which DXCC countries losing much of their territory have been deleted from the DXCC list. These favorable precedents included the deletion of Germany and the establishment of two separate countries of East and West Germany. The NCDXF also cited previous deletions in the 1960s in Africa (as the French colonial holdings became independent).

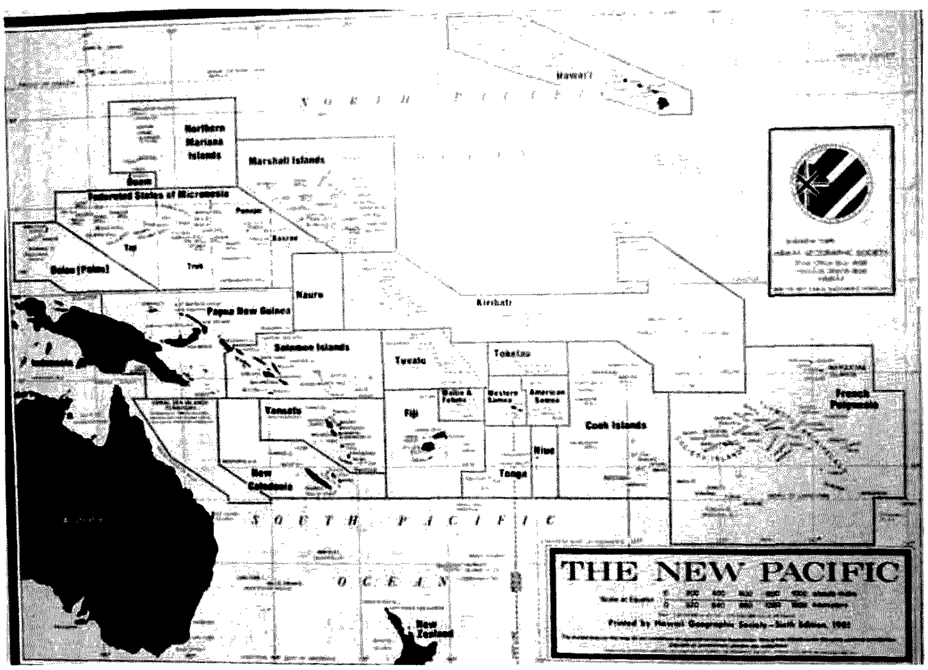
Of course, the DXCC program is not known for its consistency. The DXCC list is full of conflicting precedents. There were several cases in which DXCC countries lost significant portions of their land area and were not deleted from the DXCC list.

The NCDXF bolstered their argument with detailed land-area charts, supporting their claim that the DXCC country would lose 90% of its land area and 100% of its human population when the US gave up its control of the Phoenix group.

The argument proved telling, as, in late spring of this year, the DX Advisory Committee supported the NCDXF request. The ARRL Awards Committee will most likely approve this recommendation, and another DXCC country will join the ranks of the deleted.

Concurrent with this deletion is the recommendation to create a new DXCC country of Baker and Howland Islands. After all, these islands would no longer be part of the now-deleted country. On the other hand, the islands are too far from any other US island in the region to be part of a previously-existing DXCC country. The only option left is to establish a new one composed of the two islands, and such was the recommendation of the DXAC.

The tiny islands join several other minute and difficult-to-reach US possessions in the region. Just north of Christmas Island (in the Eastern Kiribati Republic) are the islands of Palmyra and Kingman Reef, both of which are separate DXCC countries. The difficulty and expense of reaching these isolated islands has kept them high on the Most Wanted List. And an unfortunate crash landing of a DXpedition airplane on Palmyra has caused the owners of the island to stop issuing landing permission for DXpeditioners to the island. Tiny Kingman Reef is only a



Baker and Howland Islands are located directly above the word "Kiribati" in this photo.

few feet above the waves and therefore requires a major expedition and good weather for a significant radio operation. Hence, Kingman Reef and Palmyra are among the more difficult countries to work in the Pacific.

Baker and Howland will certainly fall into this category. The islands are now a wildlife refuge under the control of a Department of Interior unit. In addition to the usual problems of transportation, generators, gear, food, and shelter, any DXpedition to the new country of Baker and Howland will have to comply with the requirements of the Interior Department not to disturb the wildlife.

The NCDXF hopes to mount the first DXpedition to this new country sometime in the near future. Given the transportation problems in the area, the DXpedition will be a major one. There are no scheduled air flights in the area except to Christmas Island (well over a thousand miles away). Even locating Howland will be a challenge, as the island is surrounded by more than 300 miles of open ocean.

One well-known individual had trouble doing just that. It was Howland Island that Amelia Earhart was attempting to locate on the last, and fatal, leg of her round-the-world flight. The last the world heard of this intrepid aviatrix was a garbled radio transmission in the vicinity of Howland, and then silence. Hopefully, the NCDXF team will have better luck finding their destination.

So the next time you hear a station from KH1, the odds are you haven't worked it before. Jump into the pileup and be one of the fortunate amateurs who works a new one on the first operation from KH1. Special thanks to Jim Maxwell W6CF, secretary of the Northern California DX Foundation, for this information.

RTTY LOOP

Marc L Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Labor Day finds us looking forward to the kids returning to school, the new fall television season, and cooler weather to work on that new antenna system. Nonetheless, many of you have offered this thought or that on your own RTTY setup. Let's see what's going on.

SSG Gary Kohtala DA2XF is using a Commodore 64 and is interested in RTTY mailboxes. He questions whether the Apple program, Super-RATT, published by Universal Software Systems, is available. Apparently he has tried to contact USS without results. Well, sorry to say, Gary, I have not seen any ads from the firm in several months. I just don't know their condition. If anyone can help Gary out, drop me a line and I will forward the information to him.

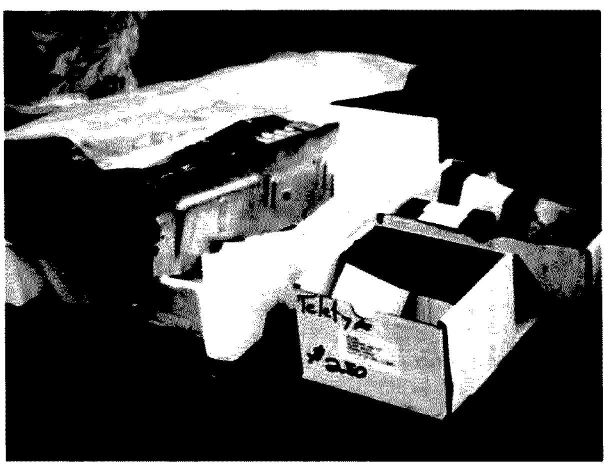
One ham who is operating a Commodore computer as a RTTY mailbox is Bob Kling K8GJL. He notes that several amateurs are operating through the 146.25/146.85 repeater in Vandalia, Ohio. While usual operations are at 60 wpm Murray, ASCII is in use at 110 baud for program transfer. Bob would like to see listings of other RTTY mailboxes in this column. So would I, Bob, but few of the system operators have sent data to me here at WA3AJR. I promise to publish all the listing and operating information I receive; just send it to me at the above address and watch for it about three or four months later in this column.

By the way, Bob, you mention in your letter that the program you are running is in Basic. How about sending along a copy and we will run it for other VIC-20 users to implement at their stations? It might even be adapted easily to other small computers. Let me hear from you.

One reader who indicates his interest in the VIC-20 on RTTY is Thomas Zeltwanger KG3V. Tom states that he has several programs available at nominal cost to run RTTY on the VIC-20. Interested amateurs should write Tom at PO Box 62, State College PA 16804, enclosing an SASE and indicating they desire information on the VIC-20 programs mentioned in "RTTY Loop."

Jim MacMurray KA2DWH is the first to write me asking about using the new MicroCoCo (Radio Shack MC-10) computer on RTTY. This computer uses the 6803 CPU, which is an intermediate between the older 6800 and the advanced 6809 which runs the "standard" Color Computer™ (TRS-80C). I would think, offhand, that any of the older 6800 programs published here in the past would run if the ROM calls were changed to use analogous routines in the system monitor ROM. I have scanned several of the specialty magazines such as *HOT CoCo* and not found anything specific to the MC-10. If any readers have interfaced their MicroCoCo to RTTY, let us all know about it.

One of our regular fans, Earl Morris N8ERO, passes along two points. First of all, his first name was misspelled in an earlier column; sorry about that Earl. With my name spelled as unusually as it is, I am rather sensitive to that and try to keep the spelling straight. Earl's question relates to the several types of ASCII that are sent on various circuits. He asks if data bits should number seven or eight, one or two stop bits, parity or not parity, or just what is the standard?



An anachronistic offering.

Well, if telephone bulletin boards are any example, there just isn't any. There are some points to be made in favor of each choice; let me tell you mine. Let's deal with parity first—most terminals ignore it. Therefore, so should you. Now, I know that parity checking is very useful, and I do use it myself on noisy lines, but if you have to deal with the great variety of terminals out there, ranging from mechanical Teletype™ machines to whiz-bang video terminals, the only practical solution is not to require parity.

Similarly, the pure ASCII code is seven, not eight bits, and unless you are transmitting data such as with an XMODEM-type transfer or graphics, seven data bits should be enough.

Now, as far as stop bits go, you should have two different schemes. When transmitting, send with two stops; when receiving, require only one. That way minor differences in speed, entirely possible with the variety of terminal programs in use, will have a bit of slack in the receiver. This was one feature of an old computer tape-storage scheme pioneering by W2NSD, and I still think it has merit. Those are my thoughts, let me hear all of yours.

I have received several letters asking for a simple AFSK generator. Fig. 1 is one such design which I have seen in various forms over the past few years. This one is adapted from an article by Clay Abrams K6AEP in the September, 1983, issue of *73*, on a RTTY program for the CoCo.

As the circuit accepts input using the RS-232 standard, let me say a few words about that. The RS-232 standard sets up many parameters for a digital signal that will be used to transmit information. Although there is much more to be specified than this, all we are going to concern ourselves with here are the voltage levels and polarities that define Mark and Space. The Mark signal shall be a negative voltage, less than −3 volts, and the Space shall be a positive voltage, greater than +3 volts.

To clarify that, with common transistor-transistor logic devices (TTL), a Mark signal is normally +Vcc, nominally +5 volts, and a Space is at ground potential, or 0 volts. With an RS-232 signal, this positive-negative relationship is reversed and the Mark is the negative signal, while the Space is the positive.

Now, I use three volts as the level, which is oversimplifying a great deal. The actual level can vary within a window from around two volts to about twelve volts. In practice, plus and minus five to eight volts should be adequate. This simple design with one chip and a few external components should be enough to put you on RTTY in a short while.

I am pleased to announce this month, the availability of the fourth in our series of RTTY reprints. For those who came in late, these are rewrites of material published in the early years of "RTTY Loop" on basic RTTY concepts. They have been condensed where need be and expanded in other areas, and are available from this address at $2.00 per issue, and an SASE. If you would like a list of topics published so far, just send an SASE to me and I will be happy to send that out. Feel free to include other comments or topics for the column with your requests; I read them all and am always delighted to hear from you.

While I'm at it, I appreciate some of the general comments offered by Bill Spann, in Mooresville, Indiana, Edward Radtke WA4BQE, in Louisville, Kentucky, George A. Collier, Jr. W5GME, in Durant, Oklahoma, Bill Pascale W8JED, in Oroville, California, Thomas Page, DDS WB7WQI, in Salt Lake City, Utah, and the many others who send me general comments, questions, and jabs which keep my keyboard popping. As I said a while back, I try to answer all mail received as soon as I can. All you need to do is enclose an SASE or sufficient US funds or IRCs for foreign countries, and send the letter to me at the address at the top of this column. While I don't publish all the questions received, I will try at least to acknowledge you in print. Of course, because of the lead time of the column, you should receive your reply before you see your name here!

In response to the clamoring for more photos from the WA3AJR camera, here is another of the sights from the 1984 Baltimore Amateur Radio Club Hamboree and Computerfest. One of the most anachronistic tables I saw was offering two items: eight-inch disk drives, and cloth ribbons for a Model 15 Teletype. The old and the new, in juxtaposition and harmony. Isn't that what RTTY really is, though? I think so, and so will you, as you continue to follow the latest here, in "RTTY Loop."

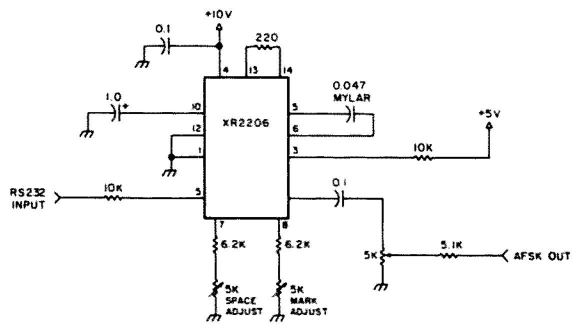


Fig. 1. A simple AFSK generator.

73 INTERNATIONAL

from page 60

is an excellent opportunity for amateur radio to obtain some free publicity, albeit restricted for the present.

One of the alternative program items at the recent conference attracted an unusual and varied following. Jazzercise, your reporter observed, attracted about 14 participants, including an attractive demonstrator, as well as about 50 "lookers" observing the merits, etc., of this type of exercise activity. I'm not too sure whether the lookers were observing "how" or "wow!"

In the Hidden Tx Hunt (Fox Hunt) contest, won by ZL3TLB's team, 3rd place went to one of our paraplegic amateurs, Bill ZL2BMQ, and his "pusher," George. As all the other competitors were on foot, Bill felt he was slightly advantaged because he was "mobile."

One of the 20 teams entered in the Mobile Rally, ZL2AA, the Gisborne team, had the only mobile antenna farm in the rally, supported by a mini-bus; the vehicle had at least a dozen aerials on or around it and I'm told the extra drag increased the gasoline account considerably.

WARO, the Women Amateur Radio Operators Club, elected Jeanne ZL2BOD of Hawera as their president for the ensuing year. There were about 35 WARO members at the annual general meeting on Sunday morning.

The Amateur Radio Emergency Corps (AREC) annual general meeting was attended by between 60 and 70 members, and various items were discussed including the Civil Defense Communications systems which are in the process of changes, as and when finances and equipment become available.

The AMSAT session included talks by Jim KA7APJ, Ian ZL1AOX, and others, giving very interesting accounts of AMSAT activities, as well as showing videos of some AMSAT happenings. There was also a video of the "Amateur in Space" showing continuously during the breaks in the conference sessions, and this attracted large crowds at every showing.

The VHF Forum chaired by Vaughan ZL1TGC and Jamie ZL2PU attracted about 90 interested members, and the subjects discussed ranged from repeater uses and abuses to packet radio. The VHF scene in ZL is very much alive and has a very good following, particularly amongst the younger and extremely talented, technically-inclined amateurs. Some of the technical features these amateurs are including in their work and projects make an old-timer's mind like mine boggle.

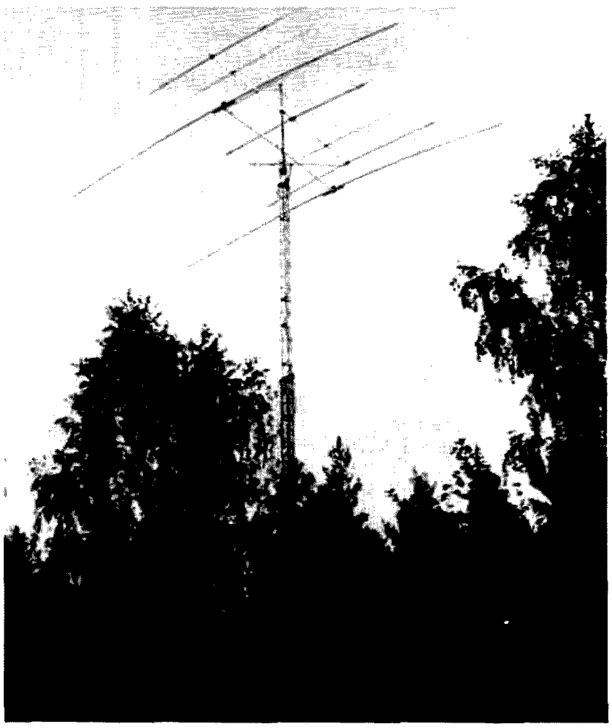
The Old-Timers Club (Quarter Century Club) also held its annual meeting on Sunday morning; about 30 members attended to discuss the business of the club. During the past year, three members received their 60-year certificates, and 33 members gained their 50-year certificates. These certificates are issued by the OTC for being licensed for the period concerned.

On the other side of the ledger, there were 15 Silent Keys recorded in the annual report; the OTC has a total membership throughout ZL of 480 as of the date of the annual meeting.

The Mobile Rally attracted entries from 20 teams and created the usual interesting and amusing incidents. All teams completed the course in good time although several got lost here and there. One team resorted to asking a policeman for directions, only to receive a very facetious reply, the officer of the law being more interested in the strange vehicle with several aerials attached thereto. The rally was conducted on three frequencies, 80, 40, and 2 meters, and consisted of three parts, operating, navigating the course against the clock with check points, and spotting detailed things from the clues given in the instruction sheet. Space does not permit listing the results, but the event was extremely successful, and I'm told there were no strained relations between team members and/or XYLs/YLs as a result of those differences of opinion which do inevitably occur on mobile rallies.

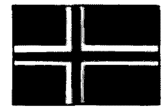
AN E-M-E FIRST

On February 18, a first for ZL was achieved when Graeme ZL3AAD, Christchurch, and John ZL2AQE, Wellington, made the first 432-MHz internal random Earth-Moon-Earth QSO. This contact was not prearranged as many E-M-E QSOs are. Graeme was using his 6-meter dish and John an array of 8 yagis. The straight-line distance between Christchurch and Wellington would be about 300 miles.



Antennas rising from the forest at LA7ZO's log cabin QTH.

Tore LA7ZO at his home QTH.



NORWAY

Bjorn-Hugo Ark LA5YJ
N-3120 Andebu
Norway

Well here we go again, folks. I'm sincerely sorry for not being able to supply any columns for a while, but this is because of illness, so you must forgive me.

Since my last, there has been quite some activity, DX-wise, and for me, the opportunity to work Kermadec Island was surely top drawer. This expedition went smoothly, as always. These guys surely do know how to handle a pileup. They proved that years ago. They are so professional that they should not be doing anything else besides giving us "New Ones." Let that be the honorable praise due them!

If the DXpedition to Kermadec was the high point, the opposite was when the news reached us that the Clipperton team was not able to go because of some unfortunate circumstances. We sincerely hope they will be able to do it again in a not too far off future.

What will I do when I've worked them all? Isn't it great to have something to look forward to!

This time I would like to present to you another friend of mine, Tore Egeberg LA7ZO. Tore has just made it into his 61st year, and is newly retired from his occupation as a 1st officer in the Scandinavian Airlines. His home QTH is situated near the Oslo fiord, around 15 miles south of Oslo. But his main operation point is at his very cozy log cabin near the lake of Kroederen, 13 miles NNW of Oslo. Facing the large lake, it is no wonder that his other hobby must be fishing. He just loves it, and rumors say he loves that more than DXing.

Tore was first licensed in 1971 and has ever since been very interested in DX. His standing in DXCC is 307 phone as of February 1, 1984. He also earned the 5-band DXCC, and was no. 4 in Norway to receive 5-band WAZ.

His home QTH, a two-story house on a 1/4-acre lot, is situated at an altitude of 100 meters topped with a 20-meter tower, a TH6DXX, and a 40/80-meter delta loop. His main operating QTH, the small log cabin, at an altitude of 160 meters, looks rather tiny beside the 30-meter crank-up tower keeping another TH6DXX and a Mosley 2-element yagi for 40 meters. Guy wires are, of course, antennas. Two slopers for 80 meters are giving him a tremendous signal on that band as well. He does, of course, have an additional spare antenna, an 18AVT with a lot of radials, and the tower also supports an inverted-V for 80 meters, up 23 meters for local (European) QSOs only. At home he's running a Yaesu FT-980 and a Drake TR7-line, and an SB-200 linear. At his cabin he has a Yaesu FT-902DM, a Swan 500 as backup, and an NCL-2000 linear. No wonder you hear him booming through the pileups.

Unfortunately, right behind his cabin a mountain rises up to 600 meters, and that direction is his very weakest point. At least there you can beat him in the pileups! But the combination of the two QTHs gives him the most out of everything, so he has, as you can see, really made his callsign heard a few times from both places.

Tore is one of those guys who fixes everything himself, and he seems to be very occupied at this time by restoring old

cars and (of course) repairing the six he has at the moment. I'm sure Tore won't be out of work even if retired. He really knows how to keep himself occupied.

You certainly will hear him on 80 or 40 meters as he loves to work DX on those bands. I'm quite sure he won't say no to a little rag-chew as well. Give him a call when you hear him.

DX

Yes, there is something going on in Norway, but at this time we will not do anything more than quote to you the official bulletin from the 3Y Project 1984/85, administered by the LA-DX Group.

DXpedition to Bouvet Island. There may or may not be experienced radio amateurs among the crew of the Norwegian scientific expedition due to start from South America before the end of 1984. Bouvet will be the last stop after approximately 2 months en route, late in the season. A landing of short duration (1-3 days) may be expected. Amateur radio operation cannot be guaranteed.

Other transportation alternatives or combinations that would be suitable for a DXpedition are being explored by the 3Y-Project set up by the LA-DX Group in 1983, with Jorgen LA5UF as project manager, assisted by Einar LA1EE.

If suitable means of transportation are found, it will be the objective of this project to organize a DXpedition to Bouvet Island in January/February, 1985.

LA-DX Group would like to get in touch with persons, organizations, or companies that can contribute to a solution of the transportation problem—a ship with helicopter(s).

It would also be helpful to know in advance of contributions, if any, in funds or in kind that may be counted on for a DXpedition of this nature.

Write: 3Y-Project Manager Jorgen Hoel, Munkerud asen 12E, 1165 Oslo 11, Norway.

The reason for this press release is that several persons have been passing fake information about where to send contributions or donations, and to once and for all establish the facts. The LA-DX Group has been working on this project for more than a year, and it is recognized officially by the NRRL and other official departments in Norway.

If you should feel that you could perhaps be helpful to the project in any way, please do not hesitate to contact the above address or, if you prefer, me. I would be more than happy to pass the information over to the project manager, LA5UF.

We know that there are many who are needing Bouvet Island, and the efforts put into this project are absolutely serious. I will, of course, keep you informed without delay if anything new should occur.

NEW CENTER OF SCOUT COMMUNICATION

Polish hams in scout uniforms enriched themselves with a new Communication Center in Losice, Miedzyrzecka 59. The Center consists of four buildings. The main building is in a reconditioned mill building. There are some schoolrooms, workshops, storerooms for measuring instruments and radio equipment, a sending/receiving center, and administration rooms. Two warehouses in Losice make it possible to store reserves.

The Center's school together with its library and radio station is in Nowosielec nearby. The carefully-repaired building rises on a little elevation. In summer, instruction camp tents can be raised all around the building. Equipment is available for 80 scouts. In the near future, two 30m masts of rotary antennas will be mounted close by. An emergency power supply makes operation of the radio stations independent. Amateur high-performance SW and USW radio stations can be installed.

What will the Center do in the future? Being well fitted out with modern measuring apparatus, the Center would provide telecommunication equipment for the Polish Scouts' Association (PSA) and prepare materials for training.

* * * * *

The presidium of PRAA (Polish Radio Amateurs Association) is preparing documents for the National Congress, delayed to the second half of 1984 because of the extending of licensing updating by State Radio Surveillance. At the last sitting of the presidium, new instructions of materials management and rules for development funds were accepted.

From January 14 to 17, 1984, the time-honored contest, "Warsaw Marathon," took place to commemorate the 39th anniversary of the Warsaw liberation. Three hundred radio amateurs all over Poland took part in the contest.

The main Inspectorate of State Radio Surveillance was informed of the resolution of WARC to render accessible to hams 10-, 18-, and 24-MHz bands, under permission of country administration. These bands, however, will not be accessible to Polish hams at present, State Radio Surveillance says. At first, we shall be able to work on 10 MHz.

In June, 1984, a symposium on electromagnetic compatibility takes place in Wroclaw. A special session for radio amateurs is foreseen within the framework of the symposium.

FALU RADIOKLUBB ANNIVERSARY

The oldest still-active radio club in Sweden is located in the capital city of the district called Dalecarlia. The city Falun is primarily known for its copper mines. The Falun mine is older than the Kingdom of Sweden, but the copper mining company received its first known official charter from King Magnus Eriksson in 1347. During the 17th century, the Falun mine was the world's largest producer of copper. No mining is done there any longer, but visitors can tour the mine down to the 180-foot level.

Falu Radioklubb was founded on February 15, 1924, but had actually functioned as a radio-listener's club a year earlier. One of the members, Ove Mogensen, was already then experimenting with transmissions. The purpose of the club was to start regular broadcast transmissions and it was issued the call letters SMZK. This activity was financed mainly through private support but occasionally paid commercials were aired.

Sweden no longer has any privately run broadcast stations due to the state-owned monopoly broadcast radio. In 1950, Falu Radioklubb changed its activities into SWL and amateur radio. The club has twice hosted the annual ham convention for the national league, SSA. The first time was in 1960, the second time this year of the sixtieth anniversary for the club. In fact, Falu Radioklubb is one year older than SSA!

FALUN COPPER COIN AWARD

The club issues a beautiful award. It is a replica of the "one dollar copper coin" from King Karl XII's 18th century. In order to acquire this unusual award, you should contact radio amateurs within the county of Falun. All QSOs have to be made in the same mode, i.e., either CW or phone, not mixed. The minimum report accepted in the exchange is RST 338 on CW and RS 33 on Phone. For stations in Zones 14, 15, 16, and 20, each QSO gives one point. All others receive 5 points for a QSO on 80 meters, 3 points on 40 meters, and 2 points per QSO on 20, 15, and 10 meters. You can count the same station once per band, and the contacts have to be verified by QSL card. However, do not send any cards with the application, just a regular GCR listing. A total of ten (10) points is required for this award. Send the application and the GCR listing to Falu Radioklubb, PO Box 701, S-791 29 Falun, Sweden. The fee is US$15.00.

7SK4AO

During a two-month period up to the last day of the SSA Convention, April 15, 1984, Falu Radioklubb could use the special prefix 7SK. The Swedish Telecommunications Authority very reluctantly issues special prefixes, but when they do, the number 7 before the regular prefix is the way they do it. Swedish hams were denied the WCY prefix last year so they do not issue special suffixes either! Anyway, maybe you managed to contact 7SK9AC in Stockholm, June 8 through 10, which is the second Swedish special prefix station for this year. The occasion was the European DX Council in Stockholm.

SPECIAL PREFIX TO SK7AX DENIED

On May 18, 1984, the city of Jonkoping celebrated its 700th anniversary. The radio club SVARK (Sodra Vatterbygdens Amatorradioklubb) issues a penant award to commemorate this anniversary. The rules for the Match Town Award were published in *73* for December, 1983, on page 154. SVARK applied for a special prefix but was denied this as "the anniversary had nothing to do with amateur radio."

THAILAND

Tony Waltham HS1AMH
c/o Bangkok Post
U Chuliang Building
Rama 4 Road
Bangkok 10500
Thailand

Director-General of the Thai Post and Telegraph Department, Mahidol Chantrangkoon, recently told a group of prominent radio amateurs at an informal get-together that he intended to legalize HF for amateur radio "by the end of this year." Acknowledging that he had the authority to legalize private amateur radio, he admitted that it would take a few months to persuade more senior government officials of the importance of the amateur service.

Radio amateurs in Thailand have—more or less voluntarily—been off the air since December 31, 1982, with the exception of legal HF operations during major contests such as the Southeast Asia Net Contest, the All Asia DX Contest, and the *CQ* Worldwide contests last year. This period of inactivity followed a warning by the previous Director of the Post and Telegraph Department to operators that they should bring their HF equipment to be disabled and sealed by Thai PTT officials. The warning came in December, 1982, and followed what had been tacit acceptance of amateur radio by the authorities, with administrative matters and operating procedures overseen by the Radio Amateur Society of Thailand, albeit in an unofficial capacity.

At that time, the previous PTT director had recently established a "Volunteer Radio Operator Network" of Thais who, after sitting and passing an examination in radio theory, had been granted licenses to operate on six spot frequencies in the two-meter amateur radio band.

The then Director-General of the PTT said that he envisaged this as a forerunner to full, legal amateur radio, but he had added that it "would take a long time, perhaps many years, before HF could be authorized."

Only Thai citizens were, and are, at the time of writing, granted permission to operate on these frequencies.

Operators were assigned a three-letter number to be preceded by the letters VR—unfortunately, the amateur prefix for British overseas territories (now only Pitcairn Island—VR6) retains this prefix. While this operation has been the nearest thing to amateur radio in Thailand, it does not conform with the IARU designation or international practice. According to these regulations, all contacts must be made in Thai and contact established first on a fixed calling frequency.

Appointed Director-General of the PTT late last year, Mr. Mahidol reportedly said that he felt that amateur radio in Thailand should conform to international practice and that he intended to authorize HF this year. However, he admitted that there were still some hurdles to overcome and that the VR service would be retained for the time being in order to demonstrate how useful amateur radio could be for the community.

Recently, Mr. Mahidol praised the VR operators for assisting the authorities during emergencies and in helping police should they witness a crime. Nevertheless, he reportedly said that all qualified amateur-radio operators should follow international law and conventions.

He also told this group of concerned Thai hams that the authorities saw no problem in issuing authorization in response to applications made by the Radio Amateur Society of Thailand (RAST) to operate during contests in the meantime.

Hams in Thailand are optimistic in the light of this frank discussion during which Mr. Mahidol gave open and well-thought-out answers to many questions regarding amateur radio and its future in Thailand.

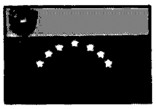
He openly criticized certain individuals who, he said, were using their influence with senior officials and were operating illegally on amateur frequencies. He said it was difficult for the PTT to enforce the law in some cases, but that he firmly wanted to see amateur radio legalized, for which

the Thai Radio Communication Act of 1955 provides.

The PTT Director-General reportedly said that foreigners who resided in Thailand and who held licenses issued in their home countries could certainly apply to operate on HF. This was taken to imply that such foreign residents, many of whom live and work in Thailand and who had been active previously, but are now not operating, would have the chance to be back on the air in the near future.

Such sanctioning of private HF operations would be a big step forward for Thailand which has opted to step firmly into the science and technological era with a Science and Technology Transfer accord signed in Washington during the Thai Prime Minister's visit there last April.

Hope to see you all on the air soon!



VENEZUELA

Luis E. Suarez OA4KO/YV5
PO Box 66994
Carcas 1061-A
Venezuela

CIRCUITO 1 (YV1)

The call area YV1, or Circuito YV1 as named here, is composed of the states of Zulia, Trujillo, and Falcon, all located in the northwest of Venezuela. Both Zulia and Falcon face the Caribbean Sea, and Trujillo, in the Andes, is facing Maracaibo lake toward the west and the plains at the east.

Alonso de Ojeda was the name of the Spaniard who discovered the now-named Lake Maracaibo, well known for the oil it produces. At that time, 1499, he didn't imagine the wealth in oil that lay under the waters he was sailing on.

Ojeda saw that the aborigines built their houses on piles over the water and that people went from house to house in canoes and on bridges and walkways. This sight reminded the Spaniard of the Italian city of Venice, and so he called it the Gulf of Venezuela (little Venice). After that, the whole territory was named Venezuela.

Lake Maracaibo is the largest lake in the Americas. It is around 155 kms long by 120 kms wide, and the deepest it goes is around 50 meters. During the 16th and 17th century, almost every buccaneer and pirate tried a raid of Maracaibo city in search of asphalt to caulk the ships. In those days, getting it out of the lake was not an easy task, as now it is.

Trujillo and Falcon

Trujillo, the capital city, was founded in 1557 by Diego Garcia de Paredes. The location of the city was changed so many times that it was once named the Portable City. The city is very small, long, and narrow, being only two blocks wide, and runs up through a mountain gorge.

The whole coast of Venezuela including the coast of Falcon was discovered in 1499 by Alonso de Ojeda. Falcon is a state of incredible contrasts. From beautiful beaches one next sees the wide coastal plain forming a small desert with light dunes, cactus, and sparse scrub thickets. Toward the south, the mountains are dressed with dense vegetation and lush forest.

Atop the mountains of Circuito YV1 are located a bunch of repeaters—9 in Zulia, 2 in Falcon, and 2 in Trujillo. Radio clubs are spread all around the main cities of those states.

Near Valencia city, in YV4-land, there is a repeater site on a mountain named El Cafe. The place is very easy to reach in a double-track vehicle. There is a site there for several dozen VHF and UHF repeaters, including many microwave links, police, fire, and civil defense two-way repeaters, plus many commerical ones.

One day, as I do regularly, I went up the mountain to inspect a couple of community repeater systems. While getting back from El Cafe, I thought about the possibility of linking amateurs throughout the whole country via 2-meter-FM repeaters. It already has been done by the telephone company, military stations, and commercial repeaters, but as far as amateur radio is concerned, repeaters have been installed without coordination.

Nevertheless, it is important to know that if you travel by car you may reach a repeater unless you are more than 200 km south and east of the Andes. And almost always you may reach more than one repeater by switching channels. At this time, two clubs have joined efforts and linked call areas 1, 2, 4, 5, and part of 3.

But, as I mentally went over the area, I went further. Why not link the Bolivarian countries? Bolivia, Colombia, Ecuador, Peru, and Venezuela all are Andean countries with the same interests, language, and history. During the trip to Caracas, I mentally looked at the map of South America trying to imagine the Andes crossing our countries. I was sure it could be done.

Back home, I took a look at a real map and confirmed that the Andes offer us the way to link the Bolivarian countries. To make things better, Panama, also a Bolivarian country, could also be linked. I was thinking about this for several days, and each new day I was much more convinced of the feasibility of this project.

During the Primer Seminario de Radioaficionados (First Radio Amateur Seminary), sponsored by Asociacion de Radioaficionados de Venezuela (ARV), it was very rewarding to hear Hebert Gonzalez YV1AHP offer to the ARV the possibility of linking one of the repeaters in Zulia state (installed by Amigos de los Dos Metros) with one of the repeaters sponsored by ARV. The offer was accepted and there is a project on the way. I asked the panel, during the meeting, about my idea—the Red Bolivariana de Repetidoras, as I thought it could be named. The panel accepted that technically it was feasible but had reservations about coordination among all five countries.

So far, I have talked with some OAs and some HKs and they thought also that it could be done.

At this moment, the project to link call areas 1 to 5 is a reality due to the effort of above-mentioned clubs. Now any amateur in Caracas is able to contact a friend in Maracaibo or a mobile in the Andeans. One-third of Venezuela is already linked via 2-meter-FM repeaters. The link is working very well—and even covers Valle Dupar in Colombia and the Antilles when propagation permits.

Here is my proposition: I wish that all amateurs in the Bolivarian countries interested in the project would drop me a line indicating how they could help. We need coordinators for each country, repeater sites, equipment, operating licenses from respective Ministries of Communications, etc. I wish to know what is already installed. We must know what is in operation on country borders and what could be used and what could not. We need criticisms, opinions, and facts (not just complaints!) and I will forward the information to both the Sociedad Amigos de los 2-Metros and Proyecto 79, since (to my knowledge) they are the most capable and enthusiastic. Besides, by the time this is published, they may have linked Venezuela from east to west along the north side of this country.

More than 150 years ago Bolivar crossed the Andes on horses and on foot without technology—just with valor and goodwill. This is not a legend, it is history. Don't tell me that we cannot cross the Andes by radio! According to my knowledge, the most difficult country to link is Peru because the Andes cross the country along its axis.

Anyhow, procedures can be developed later. At this time the most important thing is related to hardware. Maybe some links could be at 10 meters or whatever is available using FM. I think that if 10 meters is used, the mode should be FM, not SSB, for the sake of intelligibility.

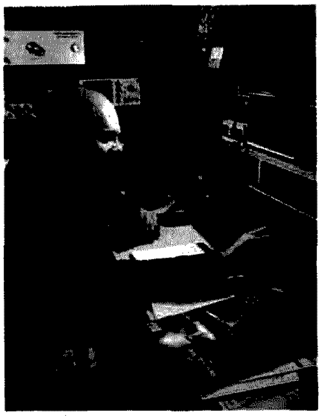
W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



ALUMNI DINNER

A ham friend, Bill Ashby K2TKN/W8ETJ, who wrote articles for my *73* magazine, mentioned back in the early 60s that he was working for a firm making microcircuits. I think his firm was one of the first in the business. Now look where we are!

Here I am, twenty years later, sitting on a plane coming back from Washington, writing an editorial on a picocomputer. Well, perhaps things aren't all that different, really. Twenty-five years ago, when I started *73*, I used to carry a Hermes Rocket typewriter, which was not much bigger or heavier than my pico (briefcase) computer. The pico has word processing and an address file, so we've had some progress.

A lot of oceans have gone under my planes since then, and the world of microelectronics has gone berserk. 256K RAM chips indeed! Solid state was still just getting started twenty years ago, though I remember buying a couple tiny Sony BC/SW radios in Tokyo in 1959. They worked great, beating the dickens out of the little US-made broadcast transistor radios. That was before integrated circuits, so they had to use eentsy resistors and capacitors.

With the 25th anniversary of my starting *73* coming up in a few months, it seemed like as good a time as any to throw a small party for Wayne Green alumni. I keep running across people in the various electronics industries who at one time or another worked for me—and there have been a couple thousand. It seemed like it would be fun for us to get together and say hello again. If you know anyone who has ever worked for me, pass along the word, okay?

In 1960, amateur radio was growing at 11% per year—and had been for 17 years. There was an intense interest in new technologies, so I thought that a ham magazine devoted to home building and inventing would fly. I had just barely enough money to print and mail the first issue, which fortunately was in the black.

I started by doing everything: soliciting articles, editing them, proofreading the type, laying out the pages, selling the advertising, writing, printing, and mailing circulation letters, typing stencils for subscribers—everything. That's quite a learning experience. I didn't have money for going to the movies or eating much, so I made do with things like homemade oxtail soup, which was very cheap.

A couple years later, I moved the one-man staff (me) to New Hampshire and started recruiting used hams. The early ones were college dropouts who worked for the learning experience, room and board, and $20 a week. They helped with processing subscriptions, printing names on wrappers, editing articles, proofreading, bookkeeping, washing dishes, and so on. I taught them publishing, sold advertising, and cooked three meals a day for the tribe. We had up to eight living in and doing the work back around 1963. We had a ball!

When we had a chance, we piled into our VW wagon and headed out for a picnic, visiting New Hampshire's Polar Caves, Franconia Notch, The Flume, Cannon Mountain, Mount Washington, and so on. We climbed Washington, swam in The Foot Basin—it was fun.

Down through the years I've fed hundreds of people into the electronics and computer industries. One runs a very successful satellite-receiving business, another one of the top computer PR firms, and several are magazine editors. A call on the PA system at the West Coast Computer Faire for ex-Wayne Green

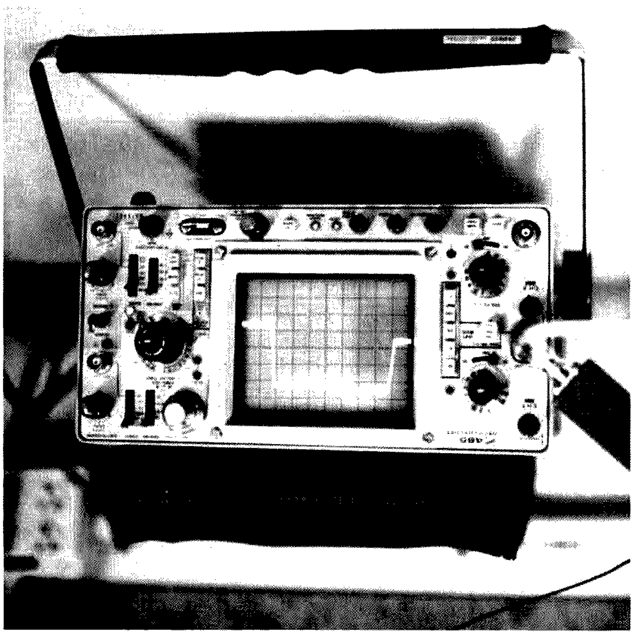
Find Fault with Your Coax

Is your cable really doing its job?
Find out with this elegant detective method.

Time Domain Reflectometry (TDR) is perhaps the most powerful method for wringing out a radio transmission line. Professional TDR instruments are expensive and therefore beyond the reach of amateurs. If you have access to an oscilloscope, however, you can build an *impromptu* TDR unit that will provide at least elementary capability.

TDR techniques can be used to locate faults on transmission lines, measure vswr, and determine the velocity factor of coaxial cable. The fault-finding capability is especially useful on systems containing very long transmission line, or, where the transmission line is hidden for much of its run.



The K4IPV home-brewed reflectometer.

Transmission Lines—Simplified and Revisited

Most amateurs have a rudimentary idea of the nature of a transmission line, especially as the term is used in radio-antenna contexts. On the naive level, we know that it is the cable which carries signals back and forth between the rig and the antenna. On a slightly more technical level, we find that the transmission line can be modeled as a complex circuit having both distributed inductance (L) and distributed capacitance (C). Fig. 1 shows an equivalent circuit. If dimension "A" in Fig. 1 is unit length, then L is the inductance per unit of length and C is the capacitance per unit of length. There is also a source impedance, R_S, which is the transmitter output impedance, and a load impedance, R_L, which is the antenna radiation resistance.

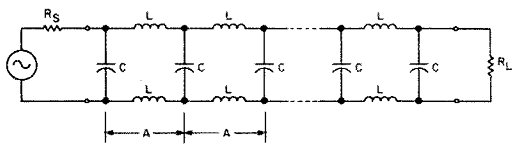


Fig. 1. Schematic representation of a transmission line.

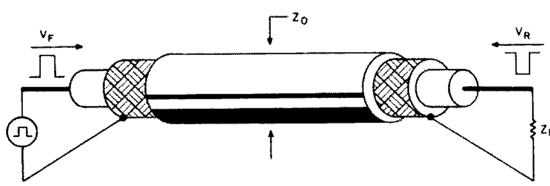

Fig. 2. Coax cable with surge impedance Z_0 and load impedance Z_L.

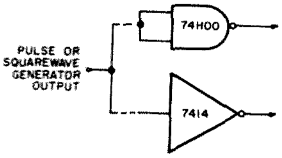

Fig. 3. Buffer to improve rise time of a signal.

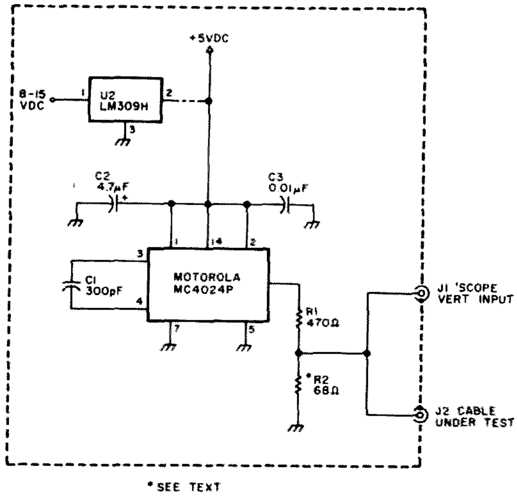

Fig. 4(a). Square-wave signal generator.

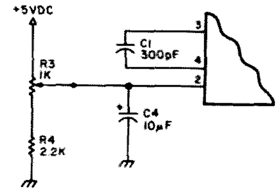

Fig. 4(b). Variable frequency modification.

Transmission lines have a property called either *surge impedance* or *characteristic impedance*, either of which is represented by the symbol Z_0. In the simplest definition, surge impedance is the square route of the ratio L to C: $Z_0=\sqrt{L/C}$.

Let's consider what happens on a transmission line; see Fig. 2. In this illustration, we have a length of coaxial cable with a surge impedance, Z_0, terminated with a load impedance, Z_L. At the input end of the transmission line is a pulse generator. So what normally happens?

We are told that the transmission line acts as if it were infinitely long when $Z_L=Z_0$. In that case, a pulse (V_F) applied to the input end will disappear into the coax and never return. In other words, the load will dissipate *all* of the pulse's energy when the load impedance (Z_L) matches the transmission line surge impedance (Z_0). This is why we put so much emphasis on a proper match between Z_L and Z_0, as indicated (hopefully) by a 1:1 vswr.

But what of the case where Z_L is not equal to Z_0? In that case, not all of the energy in the forward or incident pulse (V_F) is absorbed by the load. Some of the energy is reflected back down the line in the opposite direction. Pulse V_F in Fig. 2 is the forward pulse that is applied by the signal generator. When it hits the load end of the line, some of its energy is absorbed by Z_L and the remainder is reflected back towards the load in the form of pulse V_R. (Note that the *phase* of the V_R is reversed compared with V_F.)

Radio waves and pulses travel down a transmission line at a known velocity that is some fraction of the speed of light (c). The so-called *velocity factor* of a transmission line is that fraction. Thus, a velocity factor of 0.66 means that waves and pulses propagate in that line at 66% of the speed of light (i.e., 0.66c).

If the speed of propagation on a line is known or can be measured, and if we have a means of timing the interval between the application of the forward pulse and the return of the reflected pulse, then we can calculate the length of the line. If the line is either open or shorted, then the length computed is the distance from the input end and the fault. In a long system, such information can save a lot of hunt 'n' check work.

Signal Sources

There are two basic TDR techniques available to the amateur; one uses a real pulse and the other a square wave. Equipment needed for these techniques is rather simple, except for the 'scope.

The oscilloscope needs a bandwidth of 5 MHz or more (preferably more). In addition, it must have a horizontal sweep calibrated in units of time (e.g., µs/cm).

The signal source can be any pulse or square-wave generator, either commercial or home-brew. In researching this article, I used a Tektronix IM-500 series pulse generator, a Heath IF-18 square-wave generator, and several home-brew generators (discussed in text). It is highly desirable that the signal source have a fast rise time.

If your oscilloscope has a +GATE output, then you may already have a pulse generator. The +GATE outputs a short-duration pulse every time the sweep is triggered. In the auto-trigger (i.e., free run) mode, the sweep is constantly retriggered regardless of whether or not a signal is present in the vertical channel. Thus, we will see a constant pulse train at the +GATE output during auto-trigger operation.

If you plan to use a square-wave generator as the signal source, then it may be advisable to improve the rise time of the signal. Fig. 3 shows two buffers that can be used. The 74H00 is a high-speed version of the 7400 two-input NAND gate. This device is shown connected as an inverter (i.e., both inputs tied together). The 7400 is recommended for TTL-compatible outputs.

The 7414 used in Fig. 3 is a Schmitt trigger. As such, it will produce a fast rise-time output pulse. Like all TTL devices, there are limits to the allowable input-voltage swings. Note that the Schmitt trigger can be used to make square waves out of sine waves. The Schmitt output is binary, i.e., only two states are allowed, HIGH and LOW. The output will snap HIGH when the input passes a certain threshold voltage in a positive-going direction and will drop LOW only when the signal crosses another threshold in the negative-going direction.

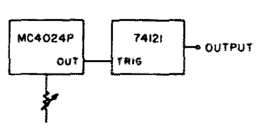

Fig. 5(a). Pulse-generator circuit (block diagram).

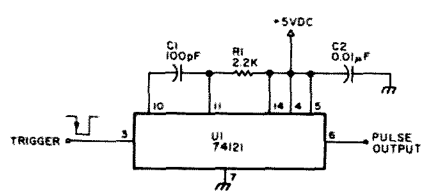

Fig. 5(b). Pulse-generator schematic.

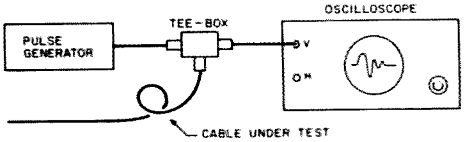

Fig. 6(a). Test setup.

Fig. 4(a) shows a homebrew square-wave signal generator based on the Motorola MC4024P voltage-controlled oscillator (vco) chip. *Note*: this is not the CMOS 4024 device.

The MC4024P contains two vco's, but this project uses only one. The frequency is controlled by capacitor C1 and is set to approximately the range needed for our application. In some cases we will want to vary the frequency, so we can use the circuit modification of Fig. 4(b). Potentiometer R3 changes the voltage applied to the vco-control input (pin 2). A 3:1 frequency ratio is possible. One use for this capability is optimization of one of the TDR techniques given below.

The output from the MC4024P device is a TTL-compatible square wave. For TDR, however, we can use almost any level within the ability of the 'scope, but the source must have an output impedance that is matched to the transmission line. Impedance matching is the function of R2 in Fig. 4(a). If only one style of coax is being tested, then set R2 equal to its Z_0 (e.g., 50 Ohms, 75 Ohms, etc.); the value of 68 Ohms allows testing in 50- *and* 75-Ohm systems with only a small effect on the system.

The photo shows the version that I built. In this case only one BNC jack is used, and an external BNC "tee" separates the signals to the oscilloscope and the cable under test. Note that the entire system, including the Pomona box, represents only a $15 accessory to a standard oscilloscope.

A pulse-generator circuit is shown in Figs. 5(a) and 5(b). Here we see a monostable multivibrator (one-shot) driven by a square-wave source such as the one in Figs. 4(a) and 4(b). The detailed circuit for the one-shot stage is given in Fig. 5(b).

A typical test setup is shown in Fig. 6(a). The interconnections between instruments is accomplished by a special tee-box—see Fig. 6(b). The circuitry is housed in a Pomona box fitted with three BNC or (if older test equipment is used) SO-239 UHF connectors. When building the tee-box, keep leads as short as possible; use "good VHF layout practices." Note that the tee-box is not needed if you build your own pulse/square-wave signal source that incorporates similar elements.

TDR Methods

There are two methods by which we can use TDR on simple systems. If a pulse-train signal source is used, we will get indications such as Fig. 7. The forward pulse, as applied by the signal source, will have a higher amplitude and sharper features than the reflected pulse. Coaxial code normally attenuates signal, so one would expect the amplitude to decrease. The waveshape also will change since this attenuation is different for different frequencies.

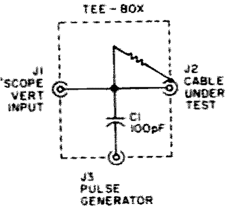

Fig. 6(b). Tee-box detail.

Notice that the reflected wave is different in (a) and (b) in Fig. 7. In (a) we see the situation existing when the transmission line is unterminated, i.e., open-circuited. Here the reflected pulse has the same polarity as the forward pulse. If there is a break in the coax line, then we will see this waveform. The situation for a terminated or shorted line is shown in (b); here the reflected wave has a reverse polarity.

The length of the line can be found from the time T required for the reflected pulse to return to the point of origin. The following factors affect T: length of the line, velocity factor of the line, and constant representing the speed of light. Our basic equation is:

$$L = 983.5VT/2$$

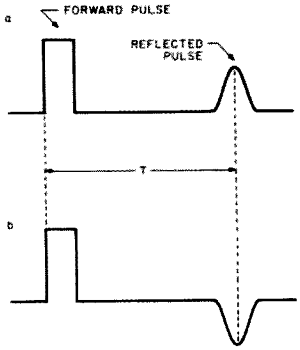

Fig. 7. TDR with a pulse-train signal source.

where L is the line length in feet, V is the velocity factor (0–1), T is the round-trip time in microseconds, as measured on the oscilloscope, 983.5 is the speed of light in feet per microseconds (ft/μs), and 2 represents the fact that T is a round-trip time.

We can rearrange the basic equation to also find T or V, as needed:

$$V = 2L/983.5T$$
$$T = 2L/983.5V$$

Let's work an example of each. Let's say we have a long piece of 75-Ohm coaxial cable used as a data line between the computer and a CRT video terminal. Your boss knows you catch bullets in your teeth and dabble in ham radio. *You*, therefore, are the resident expert and have to find out where the signal went. Being smart enough to subscribe to this magazine, you remember this article and pull it out. You obtain a pulse waveform similar to (b) in Fig. 7 and measure T as 0.63 microseconds. How far down the line is the short? First, we must determine the velocity factor. Since most TV-type coax is foam, we

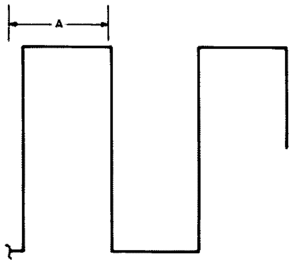

Fig. 8. Adjust square wave to match "A."

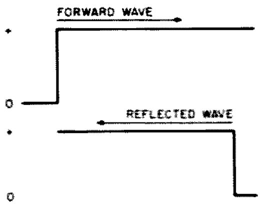

Fig. 9(a). The adjusted waveform.

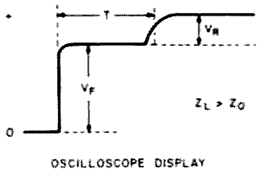

Fig. 9(b). Sum of the forward and reverse voltages.

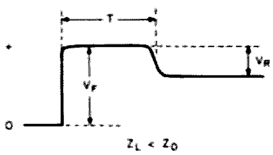

Fig. 9(c). Load impedance less than surge impedance.

can assume $V=0.8$. Therefore:

$$L=983.5VT/2$$
$$L=(983.5)(0.8)(0.63)/2$$
$$L=495.7/2=248 \text{ feet}$$

Tracing the line on the building plans, you find the area where the short should be found. Going to that area, you find a carpenter at work subdividing a room—and find the nail he drove through your coax! You hold off busting his chops when you notice the hammer in his hand.

You can use the same equation to find the length of coax needed to accomplish a specified delay. Coax delay lines are used often and are a lot cheaper than lumped-constant delay lines.

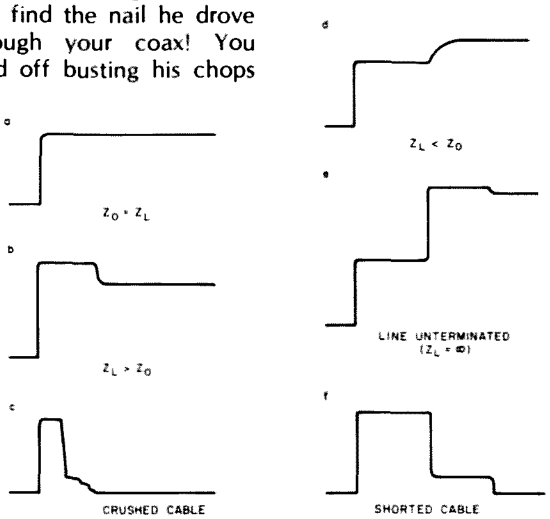

Fig. 10. A variety of traces.

It is necessary to know the actual velocity factor (V) of a piece of coax. If you are trying to make a quarter- or half-wavelength stub, then the velocity factor must be known. For noncritical applications, we can accept the common wisdom factors of 0.66 for regular cable, 0.7 for Teflon® and 0.8 for foam. But *actual* velocity factors often differ from these values, so they must be measured.

Make the measurement of T using about 50 feet of cable. The precise length must be known, and the load end should either be left unterminated or terminated in a severe mismatched impedance. This latter stipulation is needed to enhance the reflected pulse. If L and T are known, then V can be computed. If you make enough measurements on coax, you will find that published velocity factors are quite nominal and that the range of V for supposedly identical samples of cable is quite large. In fact, you may well come to doubt much of the "standard wisdom" published about transmission lines popular in amateur radio.

The alternate method used for amateur TDR uses a square wave rather than a pulse. Adjust the square-wave frequency and the oscilloscope timebase to display the top portion of the square wave as shown by dimension "A" in Fig. 8. For a perfectly symmetrical square wave, the period will be approximately 2A, so the frequency will be 1/2A.

In Fig. 9(a), the upper waveform represents the applied square wave as viewed on an oscilloscope adjusted per above instructions. The lower trace is the reflected wave.

The display on the oscilloscope will be the *sum* of forward (V_F) and reverse (V_R) voltages, such as Fig. 9(b). In the case where the load impedance is equal to the coax surge impedance (i.e, $Z_L=Z_0$), the trace will be similar to the upper trace in (a). The trace in (b) represents the case where the load impedance is greater than the surge impedance ($Z_L > Z_0$), while 9(c) is that obtained for Z_L less than Z_0 (i.e., $Z_L < Z_0$).

These traces not only tell us the direction of mismatch but also the approximate magnitude (in the form of a vswr). Using the designations of Figs. 9, we can compute the approximate vswr from:

$$\text{vswr} = V_F+V_R/V_F-V_R$$

The vswr measurement thus obtained is only approximate because transmission line attenuation reduces the reflected power returning to the transmitter end. This method, like all other methods, produces valid results only when the measurement is corrected for normal attenuation effects and the line is a multiple of half wavelength.

Fig. 10 shows the results of square-wave TDR for various situations. Fig. 10(a) shows the situation where $Z_L=Z_0$. If the system is perfect (rare!), then the upper horizontal line in (a) will be perfectly flat. If there are glitches in that portion, then it may indicate anomalies on the line. I have seen both minor crushes or bends and in-line connectors splicing sections of line cause anomalies in an otherwise perfect trace. For connectors, the glitch may be slight (especially if BNC connectors are used), but it *will* be present.

The traces shown in Fig. 10 demonstrate the wide degree of change of the trace caused by line problems. Although Time Domain Reflectometers are complex instruments compared with our simple system, our system is capable of giving us a great deal of data about transmission lines that would otherwise be difficult to obtain.■

The Aussie Parasol Beam

What has twelve corners, three bands, and uses 140 feet of wire? Hint: It's not a quad.

The Australian ham with Novice-license privileges is limited to certain frequencies and very low antenna power—somewhere in the vicinity of 20 Watts PEP. Nevertheless, many of these Novices (not necessarily beginners in electronics) produce outstanding signals all over the globe on the 10- and 15-meter bands. Some of these stations, such as VK7KDR (formerly VK7NDR), VK7NRD, VK3VGW, and others that I have worked over 100 times, have spent many hours hand-honing their antenna systems close to perfection.

During the years 1978 through 1982, when I was on the air every day, there were many VK Novice stations that *consistently* laid down S9+ signals at W6TYH. My curiosity being aroused, I contacted most of these hams and found that they were using the VK2ABQ "parasol" beam antenna described by Fred VK2ABQ in the October, 1973, issue of *Electronics Australia*.

I wish to express my gratitude to the many VK hams who mailed me photocopies of the original article and others that showed more recent modifications of this unusual antenna system.

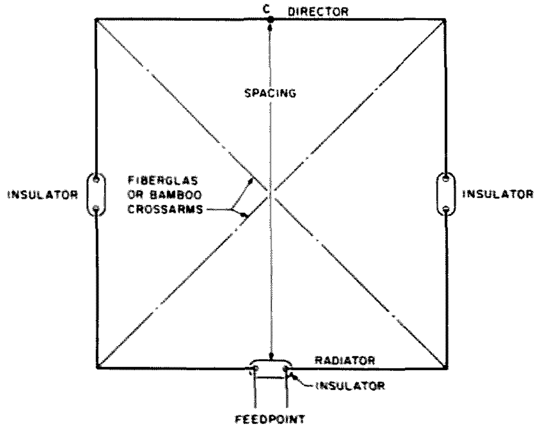

Fig. 1. Australian parasol beam antenna. Construction is similar to one frame of a cubical quad, but plane of loop is parallel to surface of the earth. Array is horizontally polarized.

One of the features of the parasol array that first caught my attention was its small, compact size. I immediately had visions of a 40-meter beam using a parasol-type loop. It is also suitable for the ham who wants a triband antenna system but is cramped for space. Because it is very light, when constructed with ordinary copper-wire conductors and bamboo or fiberglass spreaders, it can be rotated with a heavy-duty TV antenna rotator.

To satisfy my curiosity, I built and tested a dual-band parasol array with loops for the 10- and 15-meter bands only. Although the installation was not permanent, the following data should be of interest to all hams who desire a low-cost, simple, and low-weight antenna system for the three highest HF bands.

Antenna Design

As shown in Fig. 1, the parasol antenna consists basically of two wire conductor elements, each of which has its ends bent inward at right angles to the center section. Since most of the radiated field from an antenna element emanates from the center portion, the radiation efficiency is not noticeably poorer than that of a given element that used inductive traps or other shortening devices. As shown here, the parasol array is a modified 2-element yagi, using a driven element and a parasitic director.

The Australian versions of the array are fed directly at the center(s) of the driven element(s) with 72-Ohm coaxial cable. Although no specific swr figures were included in the photocopy material received from Fred VK2PHQ, I have been informed that the line swr is not greater than 2.5:1 when the three driven-element feedpoints are connected in parallel and fed from a single 72-Ohm line.

Frequency(MHz)	A	B	C	D	E	F
7.15	46' 7"	8' 2"	9' 9"	46' 7"	25'	16' 9"
14.3	23' 5"	4' 1"	4' 10"	23' 5"	12' 6"	8' 4"
21.3	15' 8"	2' 9"	3' 3"	15' 8"	8' 5"	5' 8"
28.6	11' 8"	2'	2' 5"	11' 8"	6' 3"	4' 2"

Table 1. Approximate dimensions of elements and spacing for 40-, 20-, 15-, and 10-meter parasol beam antennas.

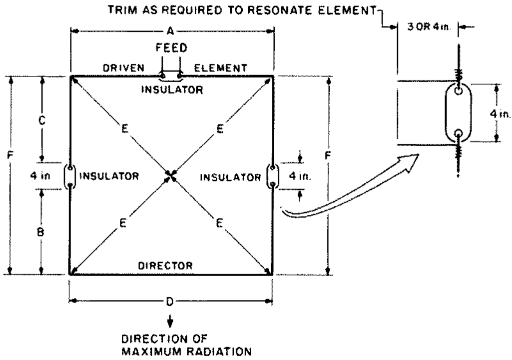

Fig. 2. General arrangement of parasol beam antenna.

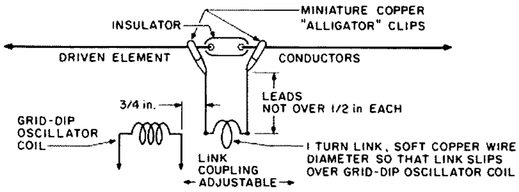

Fig. 3. How the grid-dip oscillator is coupled to the feedpoint of the driven element (see text).

In the W6TYH experimental version, the driven elements were fed by separate gamma-match arrangements, the coaxial line being switched from one to the other by a stepping relay. It should be possible to "match" the 72-Ohm (or 52-Ohm) coaxial line to the three feedpoints at a practical usable swr value by attaching a suitable coaxial line transformer to each feedpoint and connecting them in parallel at the end of the main transmission line.

The length of the folded, or bent, end sections will depend on the spacing between the driven and parasitic elements. In the W6TYH experimental version, the spacing (free space) between the centers of the driven and parasitic elements was made 0.11 wavelengths to keep the overall size as small as possible. Table 1 gives the dimensions of the parasol array for one-, two-, or three-band operation. The element lengths, particularly in the three-band arrangement, are approximate and should be "dipped" and trimmed to resonance as described later.

The approximate dimensions A, B, C, D, and E of Fig. 2 can be calculated by the following formulas. Assuming insulators I1 and I2 are 4 inches long, with F being the frequency in MHz and A to E dimensions are in feet, A = 335/F, B = 58.3/F, C = 69.7/F, D = 335/F, and E = 178.75/F.

It must be emphasized that the above dimensions are approximate but will be close to the actual operating values. The ends of the element conductors can be made about 3 or 4 inches longer than the calculated values, as shown at B in Fig. 2, and then trimmed to resonate the element at its proper frequency. In most cases, the director element will function satisfactorily when cut to the calculated value or about 5 percent shorter than the driven-element length.

Practical Construction

To start, you will need one spider or X mount, such as those used in the construction of the cubical quad antenna. You also will need four crossarm (spreader) sections, as shown. Each crossarm should be at least 14 feet long if a triband 20-15-10-meter array is to be constructed. The crossarm drilling data can be found as dimension E in Table 1. All of the wire elements should be strung on the frame before attempting any resonance adjustments.

With the array at least 8 or 10 feet above the ground, start with the 10-meter driven element and resonate it as described in the next section. Next, resonate the 15-meter driven element and recheck the resonant frequency of the 10-meter driven element. Third, resonate the 20-meter driven element and recheck the resonant frequencies of both the 15- and 10-meter elements. In the prototype array at W6TYH, the interaction between the three driven elements was negligible as far as the dip meter indication was concerned. However, when each driven element was being adjusted for lowest reflected power at its feedpoint, the swr reading changed when the matching adjustments of the other driven elements were moved.

It is likely that the greatest interaction will take place when all three feedpoints are connected in parallel and fed by a single coaxial transmission line. If the line swr is not higher than 2.5:1 on the element with the highest swr, usually 20 meters, the performance of the array will not have deteriorated to any great extent and an antenna tuner can be used at the transmitter end to present a 50-Ohm-resistance load to the transmitter output terminal.

Resonance Adjustments

As in any other parasitic array, the parasol antenna will give optimum performance only if the driven and parasitic elements are resonant at their proper frequencies. The length dimensions given for the parasitic director elements are about 5 percent shorter than those of the driven element. In the prototype array, the parasitic directors were calculated and cut according to the formula. The directors performed satisfactorily without further adjustment. The driven-element lengths required adjustment, however, as outlined below.

The preliminary driven-element adjustments are most easily made with a grid-dip oscillator and a calibrated receiver. First, make a 1- or 2-turn link coil from no. 14 soft-copper wire and with a diameter small enough to fit snugly over the grid-dip oscillator coil. As shown in Fig. 3, the link-coil ends are fitted with small copper alligator clips. Connect the alligator clips to the center ends of the driven-element conductors, as shown. Slip the

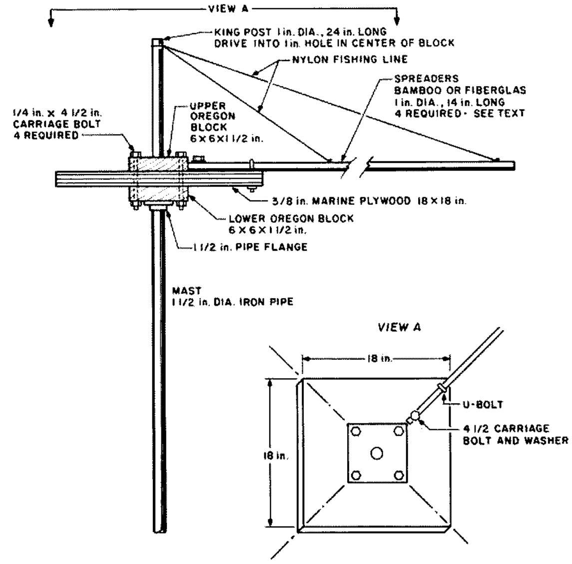

Fig. 4. Array assembly, parasol antenna.

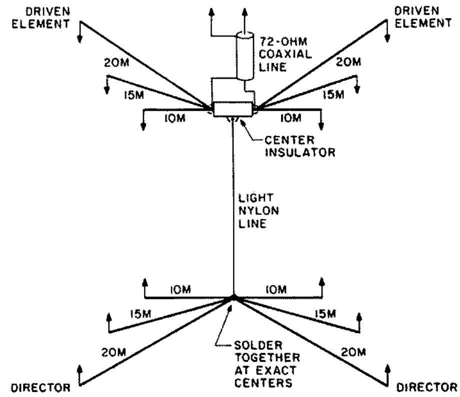

Fig. 5. Original Australian feed arrangement.

link coil over the grid-dip coil form, and rotate the grid-dip oscillator dial until a deep null or "dip" is indicated.

With the calibrated receiver, check the grid-dip oscillator at the point where the null occurs. During this first check, the resonant frequency of the driven element is almost certain to be very close to, or outside, the lower frequency limits of the amateur band. Clip off half an inch or so of the excess wire at the support insulators and repeat the process. Be sure that you check the grip-dip oscillator frequency *with the calibrated receiver* each time that a dip is indicated. *Do not* depend on the calibrations of the grid-dip oscillator dial as the oscillator will be pulled off calibration by absorption of the rf energy by the driven element at its point of resonance. This pulling effect can be reduced by reducing the coupling between the grid-dip oscillator and the link coil to the point where only a very small null is indicated.

Continue to trim each end of the driven element and check the grid-dip oscillator frequency at the null until the element is resonant at a frequency about 50 kHz lower than the desired operating frequency. The driven-element resonant frequency can then be "worked in," or "fine tuned," to exact resonance at the operating frequency during the matching adjustments.

During the adjustment of the driven element for resonance, it is possible that the grid-dip oscillator may indicate two nulls—one deeper than the other. The major null will indicate the frequency at which the driven element is resonant. The minor null will be somewhat higher in frequency and will be the resonant frequency of the director. With very close coupling between the pickup loop and the grid-dip oscillator coil, the minor null should be pronounced. When the coupling between the link coil and the oscillator coil is reduced, the minor null may not be apparent. The minor null should occur at a frequency about 5 percent higher than that of the driven element.

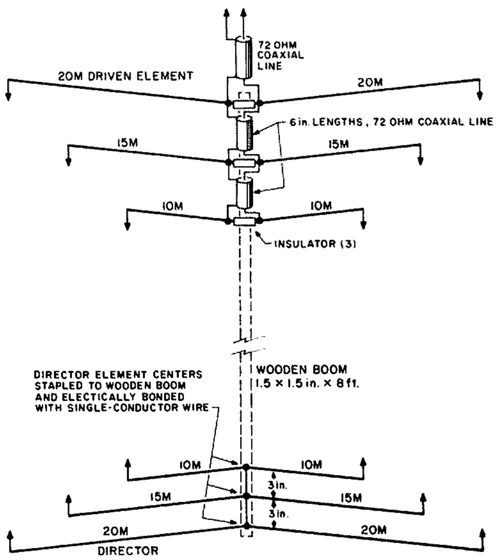

Fig. 6. Modified version of Australian parasol antenna (said to improve front-to-back ratio).

Mounting the Array

In the original Aussie version of the array, the spreaders were mounted on an 18" × 18" × 3/8" piece of "bondwood" (plywood) as shown in Fig. 4. If the plywood mount is used, it should be good quality *marine plywood*. The center of the board was reinforced by a pair of 6" × 6" × 1-1/2" "Oregon" blocks. The upper plate has a 1-inch hole at the center for the 1-inch-diameter dowel kingpost. The kingpost is about 24 inches high and is sanded to fit tightly when driven into the center hole of the upper block. In the VK version, the spreaders were made from 1-inch hardwood dowels. Most American hams will prefer bamboo or fiberglass spreaders. Each spreader is supported at two points, as shown, by heavy-duty nylon fishing line; hence the name, "parasol array."

Feed System

The original Australian feed arrangement for the three driven elements is shown in Fig. 5. Here, the three driven elements use a common center insulator with the three feedpoints connected in parallel and fed with a single coaxial transmission line. A nylon tie cord is connected between the driven-element center insulator and the center point on the parasitic director (or reflector, as the case may be) and is drawn taut. The center

points of the three directors (reflectors) are electrically bonded together.

Another VK arrangement is shown in Fig. 6. Here, a light wooden boom, 1-1/2" × 1-1/2" × 96", is used to support the driven-element center insulators. The three feedpoints are connected together with short lengths of 72-Ohm coaxial cable. The center points of the director (reflector) are attached to the wooden boom, as shown, and connected together electrically with a single copper conductor.

Antenna Performance

The W6TYH parasol array was constructed to satisfy my own curiosity, more or less. Although the antenna was a jerry-built affair mechanically and was suspended by a rope and pulley attached to an overhanging tree limb, it was electrically correct. On the 15- and 10-meter bands its performance was compared with that of a "standard" 2-element yagi similar to the one I described in "Rotary Beam for 10 or 15: the LB-2" (*73* for May, 1980), and in most cases there was little difference in the strength of the distant signal. The experimental model appeared to have about 5 dB forward gain and about 15 dB front-to-back ratio—about the same as that of the 2-element yagi used for comparison. The Australian hams rate this antenna at 5 dB forward gain, 18 dB front-to-back ratio, and 37 dB side rejection when used on the 15-meter band.

At any rate, the parasol antenna is probably the least expensive tribander. It should be possible to build it for not over twenty to thirty dollars. It can be rotated easily with a TV antenna rotator. ■

The Incredible Broadband Bowtie

Truly designed for solid-state finals, this 75m antenna features 50 Ohms at the feed—and less than 1.5:1 swr across the band.

Jim Burtoft KC3HW
RD #2, Box 131
Washington PA 15301

"Yeah, I've got a transistorized transceiver . . ."

"Do I like it? Sure, I like it a lot . . ."

"What do I think of the solid-state finals? Well, they are not as great as they sound. The finals are really sensitive to swr. I ended up buying an antenna tuner just to get the thing to load up."

If you're the owner of an all-transistor rig, you've probably had a QSO like the above. While these rigs are nice, they do have their own set of problems. Chief among the problems is their best known feature—the solid-state final amp.

Transistor rigs differ substantially from their tube-final cousins. Tube finals use an impedance-matching (pi) network to match the tube's impedance to the antenna's impedance. Transistors do things another way. Power from the broadbanded final transistor is fed through a bandpass filter into a 50-Ohm load.

Swr meter showing the swr (the tuner was bypassed).

This new system means that theoretically you can set the tuning dial to any frequency and generate a signal with no further adjustment to the transmitter. This possibility intrigued me because I enjoy rag-chewing on 75-meter phone and I operate a transistorized rig. However, a little experimenting showed me that it wasn't going to be as easy as it sounded. There's a catch.

While the transistor finals are broadbanded, they require that the load they feed be 50 Ohms or very close to it. Unfortunately, a dipole antenna is not broadbanded. Keeping the swr low as you tune across the band—that's the catch.

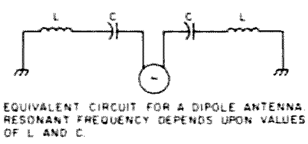

Fig. 1.

According to the theory books, a dipole should be able to cover a band equal to three percent of its design frequency. That's 100 kHz on 75 meters without exceeding a 2:1 swr. That's not much of a spread.

I decided that what I needed was a broadbanded dipole. The design requirements were:

1. Uses no exotic or expensive material.
2. Easy to construct.
3. Achieves a 1.5:1 swr or less over the 75-meter phone band.

Design requirement number one eliminated double bazookas and folded dipoles. They require expensive coax and ladder line or an impedance-matching network. I wanted to keep it cheap and easy.

As I searched, my mind wandered back to a short blurb in William Orr's *Radio*

Handbook. In his description of a tuned doublet antenna, he mentioned that the antenna could be made more broadbanded by fanning the ends of the antenna. Could the answer to my search be a simple adaptation of this idea? I decided to find out.

To start, I cut enough wire for two dipoles. The two dipoles were tied together at the center insulator while the legs were fanned one foot apart. Swr measurements indicated that I was heading in the right direction although there were a couple of problems.

The first problem was that the new combined dipole was too long. The old dipole formula just didn't work in this situation. This change was an unexpected confirmation of a lot of the antenna theory I had learned.

Remember that an antenna is equivalent to a series-resonant circuit. In fact, we could substitute a series-LC circuit for an antenna as in Fig. 1. The resonant frequency depends upon the values of L and C. If either L or C changes, the resonant frequency shifts.

Now let's go back to a real antenna. The LC relationship still applies. By spreading the ends, we have increased the antenna's capacitance. This, of course, shifts its resonant frequency. The only way to bring the frequency back is to compensate by changing the inductance, too.

Inductance is changed by shortening the antenna. In this case, the antenna had to be shortened a total of ten feet to bring the frequency back. It's the reduction of inductance, incidentally, which increases an antenna's broadbandedness.

The second problem was mechanical—how to keep the antenna in its proper position. On my first attempt, I used strips of wood to spread the antenna ends apart by about one foot, with a halyard attached at the center. This worked, but when hoisted into the air, the ends wanted to windmill, twisting the wires together and reducing capacitance.

No sweat. I just hung a brick to the bottom of each spreader. That solved that problem but created another. The whole thing took on a Rube Goldberg appearance; it was a visual embarrassment. Besides, there was the practical problem of having these two bricks suspended forty feet in the air on the ends of some rope. Needless to say, the XYL was quick to point out these problems, too.

Eventually both problems were resolved with the development of the "Broadband Bowtie Dipole" seen in Fig. 2. One look at the drawing should explain how the antenna got its name.

After numerous cuts and tries, I found that one-hundred-ten feet seemed to make the antenna resonant about the middle of the 75-meter phone band. Experiments also showed that fanning the ends more than three feet offered little or no advantage. With the ends fanned three feet, my swr was less than 1.5:1 on the edges of the phone band (see Fig. 3). Now my transistor finals perk happily along with no need to tune.

Length of the transmission line is also important. To have your transistor transceiver see the same impedance as the antenna offers, the transmission line must be some multiple of one half wave. For solid dielectric RG-58, this is a multiple of eighty-three feet.

Mounting problems were solved with the double-halyard system also shown in Fig. 2. Rope spreaders replace the original wood spreaders. Be careful not to put too much tension on the lower halyard or the whole system will be dragged closer to the ground.

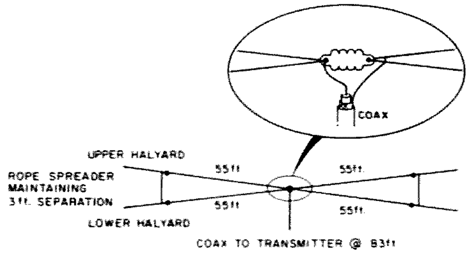

Fig. 2.

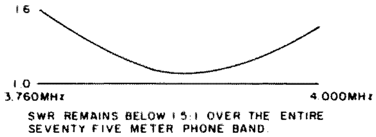

Fig. 3.

Incidentally, those interested in antennas might like to know that all antennas at station KC3HW are made from electric-fence wire. This 18-gauge steel wire comes on quarter-mile spools and is long-lasting. It's available through farm-supply stores and Sears for about ten dollars a roll.

More avenues of experimenting are open to you, the reader. How about a higher band? While I've not attempted to try the Bowtie on forty meters, it should have a flatter swr than on seventy-five.

Best of luck, and enjoy your newfound freedom. ■

℞ for Ailing Antennas

Maximize your system's performance with this easy-to-construct noise bridge. It's just what the doctor ordered.

The *antenna noise bridge* is an instrument which most amateur-radio enthusiasts have seen advertised but only a few know how to use. Several different models are offered by Palomar, Omega-T, and MFJ (see photos). When used with a receiver (preferably a general-coverage shortwave receiver), the noise bridge makes it easy to "wring out" antennas, transmission lines, and other tuned circuits.

The heart of any bridge, perhaps, is the signal source. In the noise bridge, the signal source is a noise generator such as shown in Fig. 1. The actual noise source is the zener diode connected to the base of transistor Q1. A zener diode operating in the avalanche mode produces large amounts of semi-white noise. If you connect it to an audio-amplifier input, then the output is perceived as hiss. Some people call this circuit a Gaussian noise source, but that designation is a little off the mark. True Gaussian noise contains all phases and amplitudes of all frequencies. The noise produced by the circuit in Fig. 1 is bandwidth limited to less than 300 MHz, or so. If Q1 through Q3 are selected with care, this generator produces results throughout the HF spectrum and in the VHF spectrum at least to 2 meters.

The stages following the noise-generating diode form a wideband amplifier. If the transistors are selected for UHF frequency characteristics, then the frequency response will be well into the VHF range. Good selections from the replacement lines are ECG-107 and ECG-108 or their equivalents.

Noise bridge from Omega-T.

Fig. 2 shows the actual bridge circuit. The block marked "noise-generator circuit" is a circuit such as in Fig. 1.

The heart of the noise bridge is transformer T1. There are three windings on the toroidal core of T1, and these windings are trifilar-wound. A toroidal core capable of 1- through 150-MHz operation, about 3/4 to 1 inch in diameter, should be sufficient. The wire is #28, either enameled or with the sort of synthetic material that covers wire used in wire-wrap systems. Ten to 15 turns are appropriate.

Conceptually, this bridge is similar to the simple Wheatstone bridge. Recall that that bridge contains four arms (each a resistor) formed into a diamond-shaped circuit. Excitation is applied between two of the resistor junctions while output signal is taken from the other junctions. In the noise bridge, coils L1 and L2 form two of the arms, the antenna impedance forms the third arm, and impedance R1/C2 forms the fourth arm. Excitation is through coil L3. Since L1/L2 are trifilar-wound, these two coils form identical impedances. Thus, the bridge will be in balance when the antenna impedance matches R1/C2.

Capacitor C1 has a value half that of C2. Thus, C2 will have to be exactly in the middle of its range to balance (i.e., null) the circuit. The purpose of this scheme

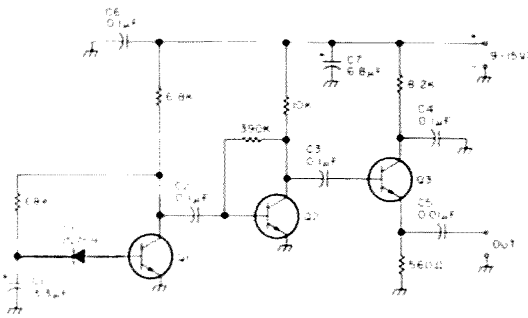

Fig. 1. Noise generator as the signal source.

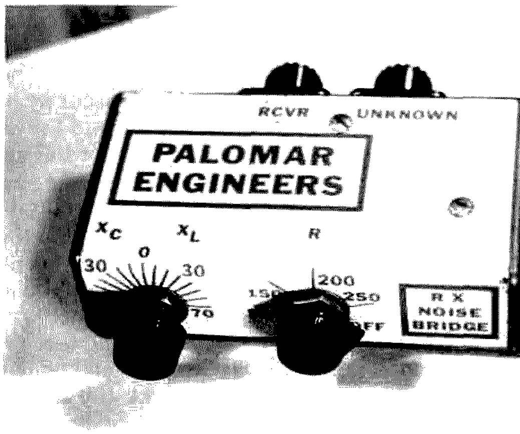

Palomar Engineers' noise bridge.

MFJ rf noise bridge.

is to allow measurement of inductive reactance components of antenna impedance as well as capacitive. Exactly at resonance, the antenna impedance reactances are equal ($X_L = X_C$), so they cancel each other. In that case, the value of C2 equals C1. If the antenna is capacitive (X_C greater than X_L), then the null is found on C2 at a capacitance less than C1. If, on the other hand, the antenna is inductive (X_C less than X_L), then the null will be found when C2 is greater than C1.

Null occurs when the impedance of R1/C2 is equal to the antenna impedance (taking into consideration C1). This null is indicated by a sudden decrease in the noise level coming from the receiver (or by a dip on the receiver S-meter). This response is shown in Fig. 3. There is usually a lot of interaction between R1 and C2, so these controls must be adjusted several times to find true null.

The null indicator is a receiver. The best type of receiver is a general-coverage shortwave receiver with an envelope (i.e., AM) detector and, preferably, an S-meter. Ham-band-only receivers require the null be inside the ham bands (often *not* the case!). I have found it difficult to use the bridge with SSB/CW modes. Tune very slowly while searching for the null. Perhaps the most common mistake made when using a noise bridge is tuning the receiver too fast. The null tends to be sharp, and is easily missed if tuning rate is high.

Finding Antenna Length

The arithmetic equations which we use to find antenna lengths are "ball park" only, except in someplace called "free space." The real physical length will be longer or shorter than the calculated length. Part of the job in setting up an antenna is cutting (or lengthening) to size. In the usual scenario, one takes a vswr bridge and measures the swr at several points within the band in order to find where the minima is located. From that information we can tell whether to lengthen or shorten the antenna.

The noise bridge gives us another method. We connect the general-coverage receiver via a short length of coax to the RCVR port of the noise bridge, and the antenna coax to the ANTENNA port of the noise bridge. Set the X control on the bridge to mid-range (i.e., C2 at half-scale) and the R control to some value between 5 and 20 Ohms (will be readjusted later). The receiver is tuned to the antenna design frequency. The procedure is as follows:

1. Vary X for a null; this null will be broad, so listen carefully and tune slowly.

2. Observe whether the X nulls are on the X_L or X_C side of zero. If the null is on the X_L side, then the antenna is too long and the actual resonant is *below* the design resonant frequency. If the null is on the X_C side of zero, then the antenna is too short and its actual resonant frequency is above the design resonant frequency.

3. Return the X control to zero.

4. Tune the receiver *slowly* in the direction indicated by the result of step 2.

5. Look for a null as you tune the receiver. When you find the apparent null, adjust R, X, and the receiver for deepest null (except interaction). This deepest null is the resonant frequency of the antenna.

6. Adjust the length of the antenna as indicated by the null: (a) if F_R is above the design frequency, then lengthen the antenna, or (b) if F_R is below the design frequency, shorten the antenna. Occasionally F_R will be so close to the design frequency that no action is needed.

The noise bridge is especially useful where the resonant frequency is out of the amateur bands. It also is useful inside the band, but so is a vswr bridge. We cannot, however, excite an antenna outside the band!

Half-wave Transmission Lines

It is frequently the case that we must excite antennas through transmission lines which are integer multiples of half-wavelength. Antenna impedance measurements, vswr or iswr, and similar measurements must be made either at the antenna terminals or through matching transmission lines which are integer multiples of half-wavelength. The reason for this is that the impedance is at the load and is repeated every half-wavelength down the line. Thus, if we measure the impedance (or vswr/iswr) through 0.5, 1.0, or 1.5 wavelength of coax, it is equivalent to making the measurement at the load (antenna) end.

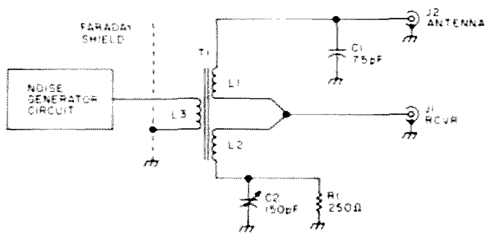

Fig. 2. Actual bridge circuit.

So how do we find half-wavelength? Some people might tell us that the length in feet is $492/F_{MHz}$, but that equation does not account for velocity factor. Since the wave velocity in the cable is a fraction (0 to 1) of the velocity in space, we must use the velocity factor (V) to reduce the physical length. The corrected length is found in Equation 1:

$$L_{ft}=492V/F_{MHz}$$

We normally use figures for V that are glibly quoted in spec sheets and antenna books (e.g., 0.66 for "regular" coax, 0.70 for Teflon™ dielectric, and 0.80 for foam dielectric). But when we actually *measure* velocity factor, we find these figures often are incorrect by as much as 25 percent—a factor that seriously affects Equation 1!

Fortunately, we can use the noise bridge to *find* half-wavelength; Fig. 4 shows how. If the coax is shorted at a point exactly one half-wavelength from the drive end, then there will be a sharp null in the noise at that frequency.

Normally, we would start with a physical length 10 percent or so longer than estimated from the equation length. We then begin shortening the coax, reestablishing the short circuit each time, until the null moves to the correct frequency. This method involves the sacrifice of a small amount of coax but yields a length that has an electrical length of exactly one half wave at the desired frequency. Some people use heavy pins or wire nails pulsed through the coax insulation to achieve the short circuit.

An alternative to the short method, as well as a check on the validity of the short method, is to use a 50–200-Ohm carbon-composition (or other noninductive) resistor in place of the short. The R dial on the noise bridge should read the same as the resistor value at half-wavelength.

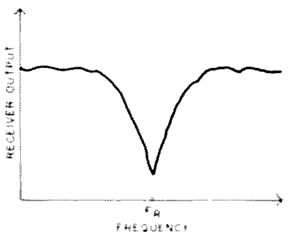

Fig. 3. Response when there is a sudden decrease in the noise level coming from the receiver.

Finding Coax Velocity Factor

The published velocity factor for coaxial cable is frequently in error. If we rely on this standard wisdom it is likely that we will at one time or another get into trouble. But it also is true that the velocity factor of any given lot of coax will have a uniform velocity factor even though it differs from the standard. Thus, if we buy a roll of cable (500 or 1000 ft. for example) and measure the actual velocity factor, then we can depend on that figure for the entire roll. From Equation 1 we know that velocity factor V is found in Equation 2:

$$V=LFN/492$$

where V is the velocity factor (0 to 1), L is the cable length in feet, F is the frequency in megahertz, and N is an integer (1, 2, 3 . . . etc.).

We can use our noise bridge to find V if we know L and can determine F on the receiver dial. A setup such as Fig. 4 is used. Measure a convenient length of coaxial cable (around 40′ will yield good results). Know (by measurement) the exact length of the cable to within an inch or two. If we assume a value for V of about 0.7, then we can calculate an approximate value for F at which N=1 (simplifies things). For example, for N=1, V=0.7, and L=40 ft., F will be approximately 8.6 MHz. We can start searching for the null at that frequency. The test procedure is as follows:

1. Set X at zero and R at just a little above zero.
2. Short the load end of the coax.
3. Adjust the receiver above and below the design frequency until a deep null is found. Record the frequency at which this null is found.
4. Using the premeasured length and the frequency found in step 3, calculate the velocity factor V using Equation 2.

You can repeat this experiment at different values of length (L) and average the results to find the "best" value of V. Once a value is determined, it can be used safely for the entire roll. You will be surprised how far removed the values actually measured are from the standard published values!

Measuring Antenna Impedance

Measuring antenna impedance with a noise bridge is very similar to the method used for finding the correct antenna length. We are assuming that the antenna is properly cut and the null is found at the correct frequency. Despite the fact that the null is on the correct frequency, it does not mean that the impedance is correct. Of course, incorrect impedance means a vswr problem.

To measure antenna impedance, we should connect the antenna to the noise bridge through a piece of coaxial cable that is electrically one half-wavelength. That way, the antenna impedance will be reflected to the input end of the transmission line where the bridge is connected. The deepest null will occur when the R control is set to the radiation resistance of the antenna. Again we are assuming that null occurs at the correct frequency. If the antenna is truly resonant, then the X control will be at zero (indicating that $X_L = X_C$). Once the impedance is known, we can determine whether or not any matching strategies are needed.

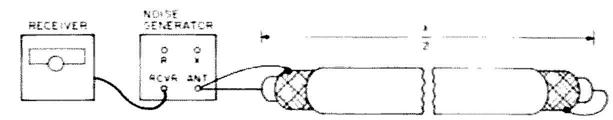

Fig. 4. Using the noise bridge to find half-wavelength.

Other Circuits

The noise bridge can be used to measure the input impedance of any tuned resonant circuit provided that the impedance is within the range of the bridge. One would not want to use the bridge on any device that is supplying power, but on passive circuits it should work nicely.

Untuned amplifiers and networks can also be tested with white noise. In those tests, one would not use the bridge portion of the instrument; only the noise-generator section is used. The circuit of Fig. 2 must be fitted with a BNC or SO-239 output connector that brings the noise signal to the outside world.

One unusual application for noise generators is in testing of signal-averaging instruments used in communications laboratories (as well as in physiology/neurology). In those applications, the noise signal and a low-amplitude sine wave are mixed in a linear summation network before being applied to the averager. If the instrument is working properly, then the noise will average to near zero while the periodic sine wave is enhanced.

The R-X noise bridge is a low-cost instrument, yet it can provide amazing results. Few items of amateur test equipment work as well or are as useful as this unfortunately neglected instrument. ■

Joseph A. Ryan WB5LLM
414 Church St., PO Box 622
Florence MS 39073-0622

Ryan's Vertical Ecstasy

Warning: Graphic depiction of vertical antenna array patterns. Explicit CoCo language. May incite construction frenzy.

Well now, this program is ideal for those desiring to experiment with designing quarter-wave vertical antenna arrays (multi-element). Formerly, unless you had the facilities of an antenna-testing laboratory available or some rather extensive equipment on hand, you had to go the old build 'n' try method.

With this program (and your trusty CoCo—see below), you can design multi-element quarter-wave vertical arrays in the comfort of your shack and construct only the final selected result. It allows you to insert up to ten elements in any layout with either + or − phasing, with any power level to any element (all referenced to a reference element), see the result displayed on a simplified Smith chart, and then call up the front-to-back ratio and gain data for the array.

This is not completely original. The original version of this program was published in the May, 1980, issue of *73*, in an article by Dennis Mitchell K8UR. It was written for the TRS-80 Model I and, to use it with the TRS-80(C)—CoCo—I found that I had to extensively revise and modify it. Eventually, I wound up redoing the graphics completely in order to take advantage of the CoCo's hi-resolution capabilities. Along the way, several features were added, like output-to-printer and distance-measurement capabilities (for converting degrees of wavelength to feet for any given frequency).

The program, as written, requires the full 32K Extended Basic version of the TRS-80(C) that's apparently in use by many hams today. However, by removing the printer option, the rather long program-operating instructions (roughly lines 960 through 1120), and several other lines (see the REM statements), you could squeeze this into a 16K Extended Basic CoCo and still have the graphic output as well as the generated data.

DISTANCE IN FEET FOR PHASE ANGLE OF 90 IS 16.42 FT.

DISTANCE IN FEET BETWEEN ELEMENTS 1 & 2 AT 7.24 MHZ. IS 32.32 FT.

DISTANCE IN FEET FOR PHASE ANGLE OF 90 IS 32.32 FT.

Fig. 1. Typical printout of two-element quarter-wave vertical array.

Program Restrictions and Capabilities

Now first of all, this is for quarter-wave vertical elements only. No multiband verticals count, as this program calculates for distance between elements and length of feedline between elements, which, obviously, change with frequency changes. However, if you're willing to build the result keeping in mind that you'd have to move the elements and lengthen (or shorten) the inter-element feedlines, I suppose they could be used. To be sensible, just plan on using straight quarter-wave elements (made out of TV-mast tubing and mounted on a soda bottle, if necessary).

Note that this program will calculate and display only the array's *horizontal-angle* radiation pattern. The vertical-angle radiation pattern is determined by your local effective ground (see references) and no provision has been made herein for that for two reasons: It probably would drastically increase the size of the program, and your effective-ground value changes daily (again, see the referenced article on ground effects).

This program will, however, calculate and display the array radiation pattern (horizontal), the F/B ratio, dB of gain, etc., for any arrangement of elements, spacing, and phasing.

Program Operation

A little about the program operation. Briefly, the various inputs requested are:

1. *Number of elements:* Anywhere from two to ten (this can be increased by changing the value 10 in line 80).

2. *Input relative phase:* In degrees from 0 to 360 (+ for leading and − for lagging). 360 degrees represents one wavelength, obviously. Two wavelengths would be 720, etc.

3. *Input angle of el.:* The direction, in degrees, from the reference element (0 to 360).

4. *Rel. amplitude of el.:* The power, in Watts, going to the element in question. (If equal to that going to the reference element from the transmitter, then the answer is 1; if less, because you're inserting an rf attenuator in the line, then a decimal value.)

5. *Input spacing of el.:* This is the distance from the reference element, in degrees (i.e., 90 = ¼ wave), to the element in question.

Finally, at each element step you're asked if the data you have input is correct. If not, you can answer with an N and enter the data for that element again. If your answer to the final element input is Y, then the program will go into the calculate mode.

While calculating, the program will go into the graphics mode and show the simplified Smith chart, displaying the elements as you have called for them to be assembled into an array. The view is "bird's-eye" (see the printout example, Fig. 1). *Be patient*—Basic takes time, and a full array of 10 elements could take 10-12 minutes to calculate.

Of course, you can insert the old "Vitamin E" poke—POKE 65495,0—at the beginning of the program listing, but I left it out because I run this program from disk, and without making internal modifications to the CoCo, the disk controller doesn't like this speed-up poke. If you're not running this with a disk system, you probably could use this poke, but, be sure to also insert the slow-down poke (POKE 65494,0) prior to any line calling for a printer output (if you use the printer option). This would speed up the calculating time by a factor of approximately 2, but for smaller numbers of elements it really isn't necessary.

When the calculations are complete, the screen will erase and then replay the Smith chart with the elements displayed and begin plotting the radiation pattern, one degree at a time, before your eyes (sound included). When finished, follow the prompt and hit ENTER for the display of power-gain and F/B ratio figures. Follow the prompt to display the menu of optional features.

The menu has eight choices. Item one will re-display the Smith-chart plot. Items two and three will display the power gain and gain in dB either every two degrees or (in item three) every 30 degrees. The latter is best for one screen display.

Item four is for a restart to calculate a new array. Item five will re-display only the Smith chart with the element placement, but no plot. Item six goes to a subroutine for calculating the actual physical distances between elements and the physical lengths of the feedlines between elements for a given frequency. This same subroutine is offered as part of item eight, which is the printout selection. Item seven simply re-displays the original display showing your input values for the original calculation. Item eight, should you elect to include it, needs several comments.

Printout Routine

Some of you may not elect to include this feature as its main purpose is to create a file of plotted antenna arrays in notebook or loose-leaf form. The sample printouts included herein (Figs. 1 and 2) show the results of the printout routine itself. If you choose to incorporate this system, you'll be prompted, after the majority of the data is printed out, for the distance calculations. The printout routine allows as many as you desire for as many frequencies as you want. Just remember that for a given array design, the pattern will not vary because of frequency because the calculations do not require frequen-

```

Fig. 2. Printout of a four-element quarter-wave vertical array showing add pattern.

cy as an input. The whole program assumes that you know how to calculate the length of a quarter-wave antenna. This distance calculation is a final touch, and allows the calculation of oddball inter-element and feedline lengths.

In order to use the printout routine, some hardware consideration must be taken. This program, as listed herein, is designed to work with a Star Gemini 10 (or 10X) dot-matrix printer. The screen-dump routine, which is not part of this program, is a commercial software product (probably sold by several companies). You may have written your own for this or have a different brand of printer (i.e., Epson, Okidata, Radio Shack, etc.). If so, the DEFUSR and USRO calls in line 1390 will most certainly be different. Use your own.

If you are using a Radio Shack LP-VII/DMP-100 printer, you can use their SCRNPRT program, but insert the correct CHR$( ) figures for expanded print, etc. (see the REM statements in the listing). In all cases, load and execute the screen-dump program prior to loading and running this one. All of this, of course, only if you plan to use the printer output.

Terminology Definitions

Wavelength: In this case, the distance in degrees (0 to 360, as in a circle) from the beginning of a wave to the end. All measurements in this program are converted into feet and inches already. If you are planning a rather gigantic array with element separations greater that one wavelength, then simply add the degrees on (i.e., 1½ wavelengths = 540 degrees). The distance-calculation option allows the calculation of the linear distance between elements, etc.

Angle of element: In this case, the location of the element in question with refer-

ence to the center of the chart and the reference element, in degrees around the compass (i.e., 45 degrees would be northeast).

Relative phase: Refers to the measurements, again as described above, except here it refers to the length of the feedline between the reference element and the element in question (or the prior element if the elements are in series).

REL(ative) AMPL(itude) of element: Refers to the amount of power this element receives (in the transmit mode) with respect to the reference element. If the power to the element in question is the same as that of the reference element, then the answer would be 1. If it is twice as much, the answer would be 2, and if half as much, .5 (here using an attenuator). In receiving-only

conditions, the answer would always be 1.

Input spacing of ELE(ment): Refers to the distance between the reference element and the element in question. This is not necessarily the same as relative phase, above.

That's it! Experiment with it. You'll get some surprises when it comes to various values you pump into the phase-angle and distance inputs as well as the layout of the array. A typical two-element array with the elements and phase angle set at 90 (and −90) degrees (a quarter-wave) will give a heart-shaped radiation pattern with a 3.0-dB gain and a 32-dB F/B ratio. Try others, including situations where the distances are less than the phase-angle figure.

Type carefully, especially from line 860 to line 950. ■

Try Low and Behold

Here's a shock: You've been wasting money on towers and poles. W1GV explains why low antennas may outperform high-altitude aluminum.

Stan Gibilisco W1GV/4
PO Box 561652
Miami FL 33156

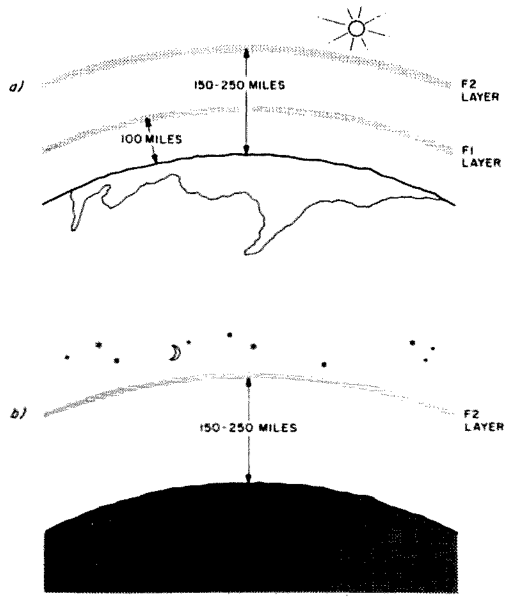

Fig. 1. During the hours of daylight, the ionospheric F layer sometimes splits into two parts, as shown at (a). These regions occur at altitudes of about 100 miles (the F1-layer) and 150 to 250 miles (the F2-layer). During the hours of darkness and occasionally during the day, the F layer consists of a single ionized region at an altitude of 150 to 250 miles.

We all have heard that the higher we put an antenna the better it will work. But this is not always true! Especially if you are a contester, you can benefit from a knowledge of how antenna height affects propagation distance.

You have just gone to a tremendous amount of trouble—not to mention expense—to put your tribander up another 40 feet. The new 90-foot tower graces your neighborhood. You drive up the street with pride. Lay persons gape at the structure with awe. A space-age communicator genius, that's you!

Finally, everything is hooked up and ready to go. You anxiously switch on the rig and tune to 14.225 MHz, getting ready for some DX. Sure enough, there's a CX3. You call him with the linear off, just for fun. A dozen others call him at the same time. You win.

A JA station calls you and tells you that you are the strongest signal he has heard so far that morning. Morning? It's 7:00 pm! Oh, yes . . . jet lag.

It works!

Now for a little domestic chatter. You tune further up the band. Strange . . . all of the stateside stations seem weak. Well, you guess, it must just be the conditions. Twenty meters can be a fickle band. You call CQ. No answer. Again. No answer.

A moderately strong W5 station is calling CQ. You answer. He comes back to someone else.

Several more failures transpire before you make a stateside contact. But he tells you that your signal is just S3. Imagine! What an insult!

Several evenings pass and half a Saturday before you allow yourself to wonder what's happening. DX seems great, but you'll get creamed in the sweepstakes.

No Coincidence

There's an old saying that something isn't a coincidence if it keeps on happening. Your new skyscraper antenna system just doesn't seem to work that well un-

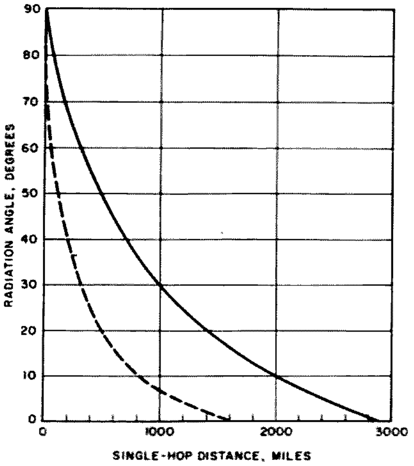

Fig. 2. The single-hop distance is related to the angle of radiation from the antenna, and also to the altitude of the ionized layer. The solid line shows the relation for the F2 region for the average altitude of 200 miles. The dotted line shows the relation for the F1-layer, for the average altitude of 100 miles.

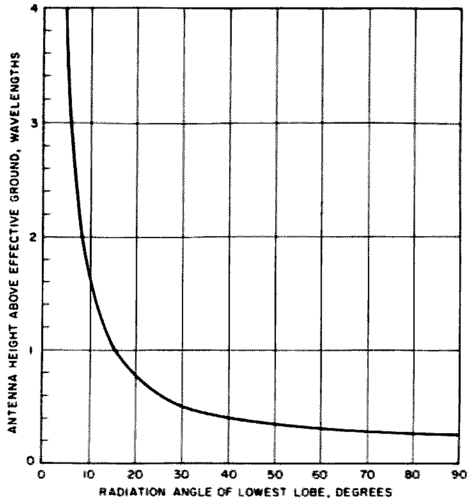

Fig. 3. The lowest lobe of radiation in the vertical plane occurs at an angle that is a function of the height of the antenna above effective ground. The lowest radiated lobe is of primary interest in most cases.

less the other station is at least a couple of thousand miles away. As the weeks pass, you begin to notice that this effect is even more pronounced on 15 meters than on 20. And on 10 meters, it is still more vivid, although it could well be the large skip zone that is responsible for the phenomenon on that band.

What causes this?

For horizontal antennas, the angle of radiation depends on the height of the antenna above the effective ground. The higher the antenna above effective ground, the lower the angle of radiation. Your antenna is high. Therefore, you can be pretty certain that the angle of radiation is low. But is that good? For DX, yes, it is good. But for contacting stations closer in, it may not be so good. Your signal might be going "over their heads."

If you are primarily a domestic contester, you can benefit from a knowledge of the way in which antenna height affects the single-hop propagation distance. By placing your antenna at just the right height so the strongest part of your signal will land in a densely populated area, you can gain an advantage over a competitor who ignores the physics of antenna height versus performance.

Single-Hop Distance

How far from your station will the strongest part of your signal come back to Earth? That depends on the altitude of the ionosphere at the time and also on the angle of radiation from your antenna.

Most propagation in the high-frequency bands takes place via the F layer of the ionosphere. This layer often breaks into two levels during the daytime; signals are then returned by a region that is about 100 miles high. At night, the F layer ranges from approximately 150 to 250 miles altitude, with the average being about 200 miles. This is shown in Fig. 1.

Since the ionized layer is usually higher at night than during the day, signal range can be expected to increase during the hours of darkness. And this is generally what does happen. If your antenna radiates most of its energy right along the horizon—that is, if the elevation angle is zero degrees—the signal will "land" about 1,600 miles away during the daytime and about 3,000 miles away at night. That's the maximum possible single-hop distance. The limiting factor is the curvature of the Earth.[1]

Of course, multiple-hop propagation makes it possible to talk with hams all over the world. In general, the lower your angle of radiation, the fewer hops are required for global propagation. That's why a low angle of radiation is favored for DX. The fewer hops your signal must take to get to the opposite side of the world, the lower the attenuation will be.

But suppose you live in Washington, DC, and want to talk with someone in New York City. If your angle of radiation is very low, most of your signal will overshoot its goal. You'll be heard very well in Greenland, perhaps, but not in the Big Apple.

The distance at which your signal "lands" after a single hop is a direct function of the angle of radiation. The lower the radiation angle with respect to the horizon, the greater the propagation distance. Fig. 2 is a graph illustrating the function of one-hop distance versus radiation angle, based on the average F1-layer (daytime) height of 100 miles and the average F2-layer (nighttime) height of 200 miles.

What Affects the Angle of Radiation?

So, you ask, how does one control the angle of radiation from an antenna at the high frequencies? The answer is that a horizontally-polarized antenna, such as a dipole or yagi, exhibits an optimum angle of radiation that varies directly with the antenna height above the effective ground plane. (A vertical antenna, assuming it has a good ground system, always radiates best at relatively low angles.)

The higher you put your antenna, the lower the angle of radiation will be, as a general rule.

We should take note that, at 160 meters, it's practically impossible to control the angle of radiation from a horizontal antenna. Unless you live in the wide-open country and still have to register your tower with the Federal Aviation Administration, you can stop worrying about the problem on that band. A horizontal antenna for 160 meters radiates most of its energy at very high angles, unless you put it at least

250 to 300 feet above the ground. That's not easy! A vertical antenna radiates at somewhat lower angles—provided a good radial system is installed. At 160 meters the installation of an excellent radial system is no small task, either.

At 80 meters, the problem still will not concern most of us. An 80-meter dipole must be at least 125 to 150 feet up for the angle of radiation to drop much from the zenith.

At 40 meters, the situation becomes different. For short-range communication, a height of 30 to 40 feet is best; for intermediate-range, 50 to 75 feet is optimum. That is not unreasonable for many hams (although for some it's an utter impossibility). For long-distance work, the old DXer's rule applies: Put the antenna up as high as you can.

At 30 meters and above, modest antenna height can result in an angle of radiation that might be lower than you want it.

How do we determine the maximum angle of radiation from a horizontal antenna, in terms of its height?

First, we must realize that the effective ground plane for radio-frequency energy usually doesn't coincide with the actual Earth surface. For flat, level ground without man-made structures, the effective radio-frequency ground plane lies several feet below the surface.[2] Obstructions such as trees, utility wires, house wiring and roofing, and steel-frame buildings can raise the effective ground plane. In an area congested with steel-frame buildings, the effective radio-frequency ground plane may be well above the level of the Earth's surface.

For the average residential dweller, the effective ground plane is probably a little bit below the actual surface. In the city where there are many tall buildings of widely varying stature, it can be difficult to estimate the level of the effective ground plane because of the irregular distribution of obstructions and because the effect of such obstructions varies with the wavelength. If your QTH is in the downtown area of a sizable metropolis, you'll probably have to resort to trial and error to find out how your antenna height affects the angle of radiation—if you have any control over the situation at all.

The effective height of an antenna is, in general, a little greater than its actual height in most suburban or rural locations. To obtain the effective height, add about 5 feet to the actual height.

Once you have determined the angle of radiation that you want, using Fig. 2, you can determine the optimum height for your antenna, in wavelengths, from Fig. 3. Where do we get Fig. 3? The signal from your yagi antenna goes out in all directions. Although much of the energy is propagated horizontally because of the directional nature of the antenna, some goes straight up and some goes straight down; some goes up and down at 30-degree angles with respect to the horizon. Overall, half of the energy is emitted toward points above the horizon and half is sent out toward points below the horizon—that is, toward the ground. The ground signal is reflected at the effective ground plane and is reversed in phase. It then heads back up into the sky, toward the ionosphere.

The familiar rule of optics applies to radio waves just as it applies to rays of light: The angle of reflection is equal to the angle of incidence. Ground reflection occurs at all possible angles of incidence; energy sent straight down from your antenna gets sent straight up, energy sent down at a 30-degree angle gets reflected back up at a 30-degree angle. Ground reflections occur over a large area surrounding your antenna.

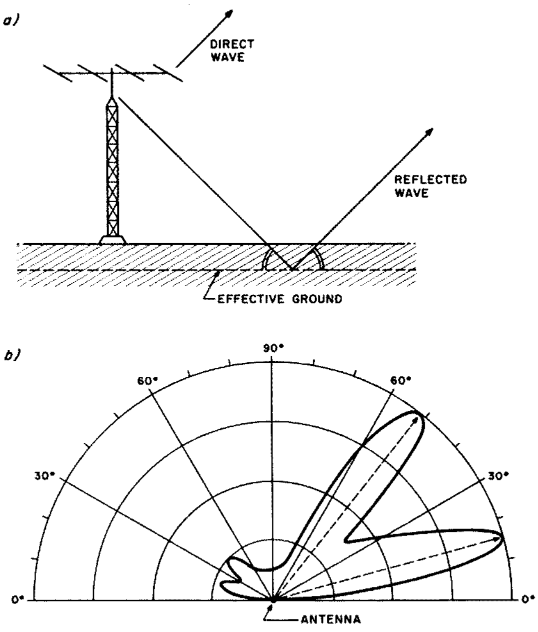

Fig. 4. The direct wave and the ground-reflected wave combine, at a distant point in the sky, in varying phase, depending on the takeoff angle. At (a) an example is shown of how these waves are emitted from a yagi antenna. At (b) a typical vertical-plane radiation pattern is illustrated for a yagi antenna at a height of a little less than 1 wavelength. (The lower lobe is of primary interest in most cases.)

At great distances and altitudes, the direct wave and the ground-reflected wave combine in varying phase, depending on the angle above the horizon. Fig. 4(a) illustrates the geometry of the situation. Fig. 4(b) shows an example of the sort of radiation pattern that occurs. This phase pattern is quite complicated, but it can be determined by simple plane geometry. The lowest lobe—the one that occurs nearest the horizon—contains the most signal energy of any lobe. The angle at which this lobe occurs, as a function of the height in wavelengths, is the lowest angle at which the direct and ground-reflected waves add in phase. It is this angle, as a function of the antenna height in wavelengths, that is shown in the graph of Fig. 3.

Optimum Angle Versus Height in Feet

Most of us have antennas that stay at the same height all of the time. Variable-height towers exist (but those of us who have "crankups" generally think of such towers more as "crankdowns"—to keep the neighbors from suing for half the gross national product because of the eyesore), and from the above discussion it should be evident that they can be used to advantage in medium-range operation.

Your antenna height in wavelengths can be determined by a simple formula, assuming you know the frequency or wavelength and the height of your antenna in feet. The following formula applies, letting h represent the height in feet above the actual ground surface, f the frequency in megahertz, and y the effective antenna height in wavelengths: $y = (h + 5)f/984$.

For example, suppose your antenna is 50 feet above the ground surface. Then the height in wavelengths above effective ground, at 14 MHz, is $(50 + 5) \times 14/984$, or 0.78 wavelengths. At this height, the optimum angle of radiation from your antenna can be determined, from Fig. 3, as approximately 20 degrees.

Now, using Fig. 2 you can find the one-hop distance for F1-layer or F2-layer propagation. During the day you should expect a distance of pretty close to 500 miles via the F1-layer, assuming this layer is ionized at that time. (If not—and the F1-layer is not always ionized during the daylight hours—the propagation will occur via the F2-layer.) At night or if the F1-layer is not ionized, you can expect the propagation distance to be about 1400 miles.

Let's try this in reverse. Suppose you want to keep a schedule with a friend whom, after you have checked on a map with a ruler against the mileage scale, you have determined is 1640 miles away. You decide to try 14 MHz, since that band has been pretty good lately. How high should your antenna be, assuming you want to have the sked at 9:00 pm?

Look at Fig. 2, at the F2-layer (nighttime) line, and you can see that the optimum angle of radiation is about 15 degrees. How high should your antenna be? Checking Fig. 3, you can see that the height should be just about 1 wavelength above effective ground.

Now, we must convert this value to feet. The "inside-out" version of the above formula can be used for this purpose: $h = 984y/f - 5$. At 14 MHz, with $y = 1$, we have $h = 984 \times 1/14 - 5$, or $h = 65$ feet. This isn't terribly high. If your tower is 90 feet high, you may well overshoot your target.

Conclusion

Neither the ground nor the ionosphere is perfectly predictable. Certainly there will be exceptions, in practice, to the guidelines given here. The most notable exception is that the F1-layer may fail to ionize during the daytime and you cannot tell until you find out by trial and error. The ionized layers vary somewhat in height, as well, and thus the above formulas are not exact. The effective ground plane in your location may not be exactly 5 feet below the actual surface.

We are dealing with variables. But it is certainly better to have some idea of how high you should put your antenna, instead of no idea whatever, or a grossly erroneous notion. The above information should give you a very good idea!

Probably the best approach for optimizing antenna height is the crankup tower or, better still, a mast or tower with an electric motor so you can raise or lower your antenna by remote control from the station. This would allow you to actually listen to the signals from a certain area, and thereby optimize your antenna height empirically (after getting the general idea by using the graphs and formulas given here).

Antenna height is, at the high frequencies, only slightly less important than the direction in which it is pointed. We would not think of pointing a yagi west if we wanted to work a station to the south of us. Similarly, an antenna that is far too high (or, less frequently, not high enough) can detract from the signal strength. The contest operator, especially, should attempt to optimize the antenna height as well as its direction. A slight edge can, as we know, make a big difference. Number 2 differs from 1 by 100 percent! ■

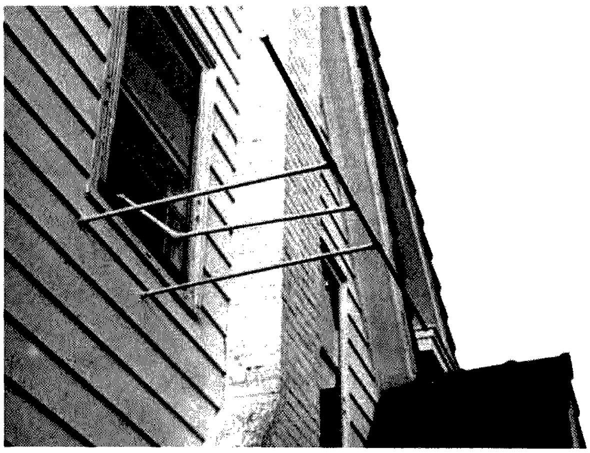
A No-Holes Barred Beam

What to do when the lease says "no antennas": Turn your entire house into a broadside dipole.

Problems common to amateur-radio operators who rent homes or apartments or live in condominiums or townhouses are restrictions on antennas. I rent the house that I presently live in and miss the freedom to put up towers or antennas indiscriminately. However, I have not given up. Examples of my past solutions to this antenna problem (for the microwave spectrum) have been reported in this journal.[1]

A more recent antenna project was to improve reception of a distant channel 2 television station. The station, in North Carolina, is the only station within 150 miles that carries "Monty Python's Flying Circus"—a program to which my wife and I are thoroughly addicted. Our landlord, who has a strong distaste for Monty Python humor, will not permit a three-element beam for channel 2 to be mounted on the chimney. What does this have to do with amateur radio? Channel 2 is close in frequency to six meters, and the antenna presented here can easily be scaled for six-meter, 10-meter, and 15-meter operation or scaled up in frequency for 2-meter or 1¼-meter operation.



The window-mounted VHF antenna.

An essential element of the design of this antenna is the design of the house. My house meets the two design requirements. First, one side faces the television station that I wanted to receive. Second, the house has aluminum siding. Up to this time, I had considered the aluminum siding to be a drawback. What amateur-radio operator wants to live in a shielded box? But now I had a use for the siding; it forms a reflector screen for a single-element broadside antenna—see Fig. 1.

The driven element is a half-wave folded dipole. (Even though the antenna is used only for reception, the active element is called the driven element.) The folded dipole is made from 300-Ohm twinlead. The length of the folded dipole is found by: L (ft.) = 492/f(MHz) × .95 × .82. The factor 492 accounts for the speed of light in English units, fringing effects are represented by the factor 0.95, and 0.82 is the velocity factor of common television twinlead. If open-wire construction is used, omit the 0.82 factor.

The driven element is fed with twinlead although the feed impedance is probably closer to 200 Ohms. A 4-to-1 coaxial balun would probably result in a good impedance match to 50-Ohm cable. The driven element is spaced 0.2 wavelengths in front of the siding; S (ft.) = 984/f(MHz) × 0.2.

Simple enough? Yes, but the hard part is how to construct and mount the antenna without drilling holes, and still be able to rapidly erect or remove it. The solution I found is shown in Fig. 2.

A frame is constructed using PVC plumbing tubing. This modern synthetic material is cut easily with a hacksaw and spliced with a fast-curing cement. Remember when glue and paint would dry? Now it cures, hardens, fuses, or passes through some chemical metamorphosis! Anyway, T fittings, elbows, 45-degree bends, and end caps are readily available at most hardware stores.

The frame hooks onto

the windowsill and is held spaced away from the house by two legs. The legs have end caps to prevent them from marking the siding. The folded dipole is inside the long horizontal piece. The feedline is inside the center leg. The antenna shown was constructed from ½-inch (inside diameter) white tubing. The white tubing is almost invisible against the white siding. For ten-meter or longer wavelength bands, I would recommend one-inch or larger tubing. For six-meter and higher frequencies, I would stay with the cheaper ½-inch tubing.

The central leg was fabricated first. After the feedline was threaded down the tubing, the driven element was soldered to the feedline. The driven element was laced to a long, thin wooden stick to prevent it from twisting. Then short sections were added to each side, the spacer legs added, and finally the end sections cemented on, complete with end caps. The completed antenna quickly hooks in place. When not being used, it is lowered with a cord down behind the bushes.

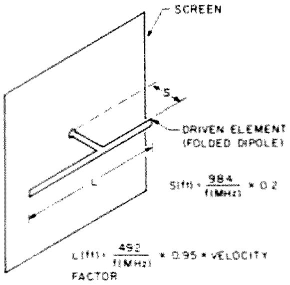


Fig. 1. Single-element broadside antenna.

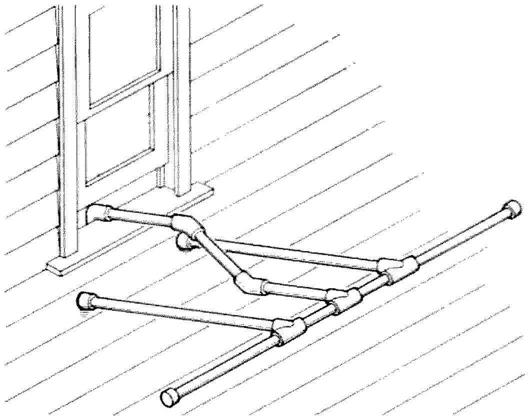

Fig. 2. PVC window mounting.

The antenna has been a complete success and is still in use. The total cost including cement, tubing, and twinlead was less than fifteen dollars. The design can readily be scaled to amateur frequencies. One could be mounted on each of four walls to achieve omnidirectional coverage. The beam pattern can be widened by increasing the dipole-to-wall spacing to three-eighths wavelength. The center and spacer legs could be left uncemented and assembled with a lock pin or screw to allow the antenna to be collapsed enough to pass through the window and eliminate lowering it down after use. (Because of the way siding is mounted, this method is usable only for horizontally-polarized antennas.) Build one and let me know how you like it. ■

Another Eggbeater

Don't be a VHF weakling. Pump up your performance with this simple 2m omni.

John Steidley WD5DNL
Rt. 2, Box 356
McAlester OK 74501

Many two-meter antenna construction articles have appeared in the past, probably more than necessary. Even so, here is my adaptation of an antenna from the April, 1971, issue of *QST*. The antenna was called an eggbeater. It is two full-wave loops mounted at right angles and fed 90 degrees out of phase to produce an omnidirectional, horizontally-polarized antenna. The round loops were changed to the more familiar square configuration. The feedline is attached to the side to produce vertical polarization. The phasing and feedlines are twinlead (300 Ohms). The balanced line is brought into the shack where a tuner is used to match to 50 Ohms.

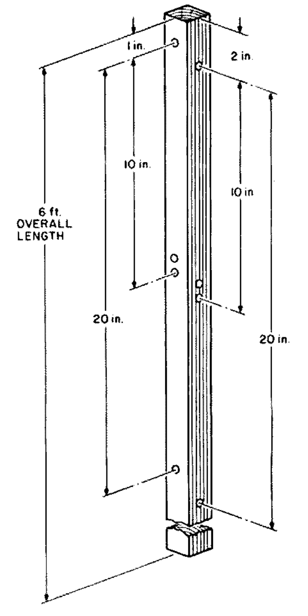

Fig. 1. Center-support drilling guide.

Construction

The antenna uses a six-foot piece of wood (1″ × 1″) as its center support. Two twenty-inch cross pieces are used (I used scrap pieces of molding, but 1″ × 1″ wood will work just as well).

In preparing the center support for mounting the elements, it will be necessary to drill two holes at the top at right angles to each other. See Fig. 1. The exact size will depend on the type of wire used for the elements; just make the holes large enough for a snug fit. Measure twenty inches down from each of the top holes and drill two more holes for the bottom of the wire elements. See Fig. 1. Mount the twenty-inch cross pieces ten inches from the top holes. Use two small screws to fasten each boom to the center support. See Fig. 2.

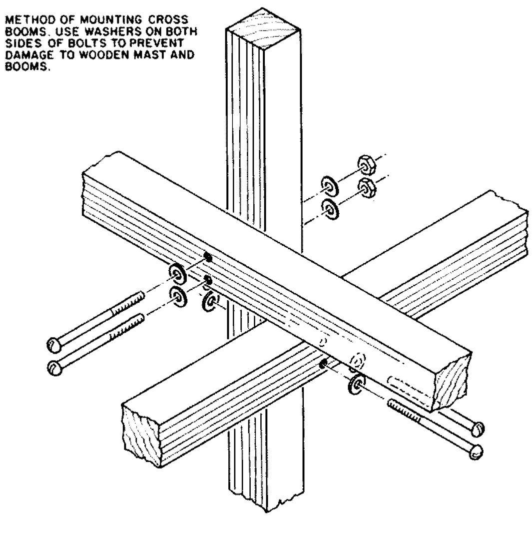

Fig. 2. Cross-boom mounting method.

Feedpoint insulators are Plexiglas™, three inches long and one and a half inches wide. These are attached to the cross booms with small screws. Holes are drilled one inch from each end of the Plexiglas insulators, and the feedline and wire elements are attached here. See Fig. 3. You can use solder lugs and screws to hold these wires to the insulator (or washers and screws). The first method with soldered connections is recommended.

Insert the wire for the elements in the holes and bend them into a square shape twenty inches on a side. See Fig. 4. Use #12 copper, either bare or insulated. You can use a larger size of aluminum wire, but this will make it necessary to experiment with the length to achieve resonance. The wire used in this model is #12 copper that is 81 inches long and was salvaged from a piece of electrical service wire.

The feedpoints for the antenna are attached to the insulators and the opposite sides of the loop are held to the cross booms with fishing line. See Fig. 4. Two small holes are drilled and the fishing line is wrapped around the element and the

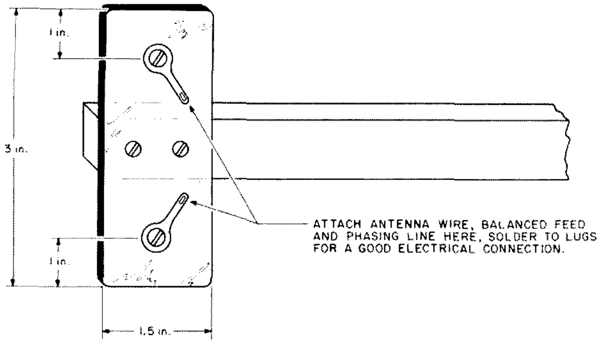

Fig. 3. A Plexiglas™ insulator.

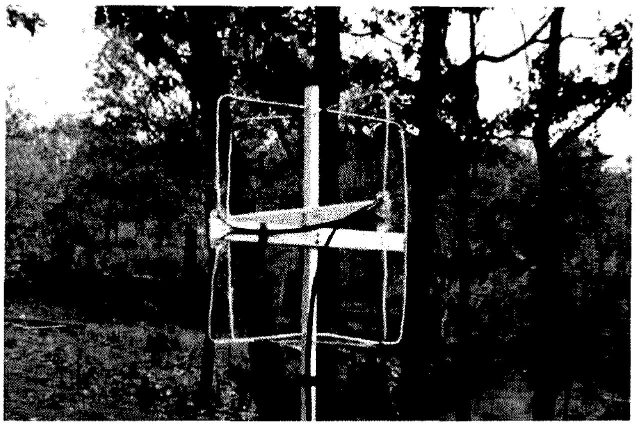

The vertical eggbeater for two meters.

boom about ten times at each hole. A dab of epoxy glue covers the wire and fishing line.

Attach the phasing line between the two feedpoints. I use twinlead sixteen inches long. The main feedline is also 300-Ohm twinlead and is connected to either element. The feedline is then taped to the wooden center support. See Fig. 4. Electrical tape is used to secure the phasing line also. *Standoff* insulators are used on the metal parts of the mast.

Conclusion

Use a good grade of twinlead and plenty of standoffs to preserve the balance of the line. Weatherproof the wood used (several coats of paint or spar varnish will do). Let me point out that it isn't necessary to use wood. One model of this antenna used PVC for the center support and cross booms. I use ten Watts of power and have encountered no problems. With higher power you may need to use the transmitting type of twinlead or open-wire line.

While the antenna won't outperform even a small yagi, it doesn't require a rotor to aim the antenna; it has been a great improvement over the various ground planes and vertical dipoles I've used in the past.

I haven't tried stacking the vertical eggbeater, but it should give some gain and a lower angle of radiation. You've got to admit the price is right, so build one or even stack two or more, and enjoy. ■

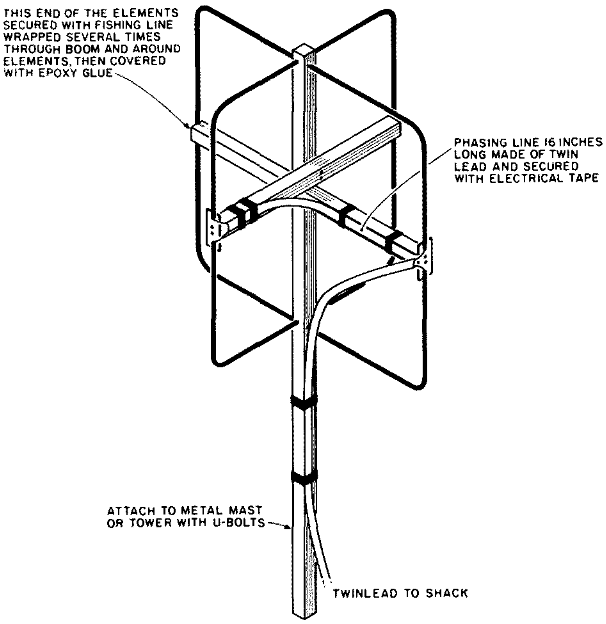

Fig. 4. The finished product.

Parts List

2 #12 copper wire—81 inches long
1 1" × 1" wood—six feet long
2 1" × 1" wood—20 inches long
2 Plexiglas™ for insulators—1.5" × 3"—use the thickest type you can find.
Screws, nuts, and washers to mount the insulators and booms
Solder lugs and standoff insulators (if balanced line is used)
U-bolts to mount center support to mast

Most amateurs accept "pirates" as a fact of life on the amateur bands, and some pirates have eventually become well-known amateurs after they have realized what they are missing by running unlicensed operations.

But when a well-organized pirate operation starts to put pressure on the powers that be for a slice of the twenty-meter band just above the amateur allocation, you start to wonder what's going on, and why.

I am speaking, of course, about that ever-growing band of yachtsmen and women who are using amateur transceivers instead of (or with) their commercial gear. It has become so bad in the Pacific that they even have their own frequencies set up on twenty meters for rag-chewing, with some of them using false callsigns for contacts within the amateur bands.

It has come to the stage that the WIA and NZART have issued a joint statement, with the backing of both the Australian and New Zealand Government Communications Departments, condemning this practice.

There have been many times, of course, that amateur radio has come to the aid of yachtsmen in distress, and this may be one of the reasons why some are buying amateur gear as backup equipment for their boats. But if, as found just recently in Australia, they are buying amateur gear *instead* of the type of approved commercial gear that they should have on board, because it is cheaper, it is not only cents wise and dollar foolish but downright dangerous, as amateur gear is not designed for this type of operation—such as being caught in a howling gale and doing a couple of 360-degree loops with salt water flying everywhere. Commercial-type, approved yacht radios are built to stand this, but amateur gear is not; that is why the commercial marine radios cost more.

However, as with any occupation or endeavor, there is always the shady character out to make a fast dollar regardless of the risk to other people or the cost to the community.

One such unscrupulous dealer in New South Wales (VK2) found a good market in selling general-coverage transceivers designed for amateur use (but also converted to cover yachting frequencies) to some members of the yachting fraternity at a lot cheaper price, due to an import tax of only 2% on this type of general-coverage gear. This practice was soon noticed by a local manufacturer of radios designed for commercial application, and he complained to the Government, to protect his own business.

The reason amateur gear drew an import tariff of only 2% was that there was no manufacturer of amateur gear of this type in Australia, so it did not compete with local firms. In this case it did, and the result was that our government immediately put a 30% import duty on all amateur transceivers being imported into this country.

One sure way to get anybody to sit up and take notice is to hit him where it hurts, and with most people, including amateurs, that is in the hip pocket. Taking all the extras into account, the final price to the amateurs would have risen around 45% on all imported transceivers.

On July 6, 1983, the WIA, plus representatives of the major importers and distributors of amateur gear, a customs agent, and an editor of a local commercial amateur-radio publication held a meeting to seek facts and advice on how to handle this tariff rise. The WIA, after many submissions plus work on their members' behalf, came up with a solution agreeable to the government. The whole issue hinged on a tariff bylaw that contained the words "without substantial modification."

The submission to the government by the WIA was that they would set up a panel of paid members who have a radio engineer's background to type-approve amateur transceivers entering this country and issue compliance certificates, to enable retention of the 2% import tariff for amateur gear.

As you can imagine, this was no easy decision by the WIA, on behalf of its members, with a lot of on- and off-air discussions both for and against the WIA being involved in this type of endeavor. However, the WIA will remain impartial at all times regarding any decision made by this panel, and will not only accept but back its recommendations.

An excellent article by Bruce R. Bathols VK3UV, the Federal President of the WIA, in the February, 1984, *Amateur Radio* (the official publication of the WIA) gives the definition of what is required to cover the bylaw that states "without substantial modification," and explains how the WIA arrived at the criteria needed.

Excerpts:

1. We recognize that any piece of radio equipment can be made to operate on any frequency providing the person attempting the modification has the correct tools and equipment, and the knowledge of performing same. As a yardstick in this regard, we accept that an amateur of at least ten years' standing would have the necessary experience to analyze circuits and equipment, and perform an actual conversion.

2. Therefore, a "Difficulty Factor" can be determined in conversions. An experienced amateur, as noted above, would be expected to relate his efforts directly to the costs of the components required, time, and effort. A monetary figure would have to be placed on the time element, therefore commercial costs of repair rates and time would of necessity be applicable in this case.

3. As far as the WIA is concerned, our only requirement is to determine in the "Amateur Sense," what a substantial modification is. We are NOT concerned with commercial conversions or sales outside the Amateur Service. (We cannot stop them anyway.) A highly-experienced professional engineer would, no doubt, be able to convert any piece of equipment to be used on other bands in a very short time. As we are only responsible to the Amateur Service, only normal amateur-type methods will be used by our technical committee in determining a conversion difficulty factor.

4. The objective, therefore, is to establish whether or not a conversion by an experienced radio amateur is able to be performed at a relatively cheaper cost than the payment of the actual tariff duty on the FOB cost of the equipment under consideration. A ratio between these costs can then be determined.

5. The ratio (a "Difficulty Factor ratio") will enable the WIA to decide whether or not a certain transceiver comes within the scope of the bylaw provisions. In this respect, only transceivers and transmitters designed for use by the Amateur Service and being imported by a recognized retailer or dealer of amateur equipment will be eligible for a WIA evaluation. Bona fide travellers bringing equipment into Australia purchased from overseas for their own personal use, will also be able to be included in the above.

It can be seen by the above just how much work, plus money, is involved by a national body representing its members in fighting repressive laws, whether they be added taxes, antenna-tower legislation, or loss of amateur frequencies. This is why it is imperative that those amateurs who sit on the sidelines as nonmembers of a united national amateur body representing ALL amateurs get their priorities right, or they could be paying an extra $800 for a FTI-type transceiver—as we nearly were. A small annual subscription is small price to pay to present a united front against anything detrimental to amateur radio.

How would it be if we all sat back and did nothing? I doubt if we would, with today's commercial pressure, have an amateur-radio service.

Adilson Ribeiro PY1AKM (left), Paulo Malavota PY1OZ (LABRE RJ Director), and Paulo Roberto Domingos PY1ZT.

RADIO AMATEURS OPERATING THE HALF MARATHON

For first time in Brazil (and we never heard about this anywhere else before) two radio amateurs joined the "Race of the Bridge" and put it on the amateur-radio air.

The Race of the Bridge is a yearly competition, a cross-country "half marathon," organized by the CORJA (Rio de Janeiro Runners Association) and sponsored by the Bradesco-Atlantica organization, a bank and insurance company helping amateur sports.

This 22,400-meter-long race (a "half marathon" as it's called here) crosses the longest concrete-built bridge in the world, The President Costa e Silva Bridge, 14 kilometers long, joining Niteroi City to Rio

de Janeiro City. It is 75 meters high at its highest point over wonderful Guanabara Bay, a dream scenery never to be forgotten.

Starting from the "Boat Station" in Niteroi and finishing at the Modern Art Museum, right in the heart of Rio de Janeiro City, this year's Race of The Bridge involved 2200 participants. There were 5 age categories: 15 to 19 years, 20 to 29, 30 to 39, 40 to 49, and 50 years on.

Two enthusiastic runners, Adilson Ribeiro PY1AKM and Paulo Roberto Domingos PY1ZT, brought the idea to our radio amateur league, LABRE RJ (Rio de Janeiro branch), and it had the immediate approval from Paulo Malavota PY1OZ, Sectional Director, so plans and action made it come true; equipment, land support, and instructions were settled on to do the best.

Running together, side by side, using a portable IC-2AT perfectly tested, with completely charged batteries, operating by turns, Adilson and Paulo Roberto carried out this so-successful operation, the first in Brazil!

Land-based station PY1AA (LABRE RJ official station) was responsible for all QSO appointments and QSL managing, runners Adilson and Paulo answering only to VHF contacts during the whole race.

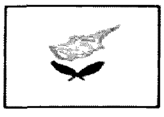
Promotion for the Race of The Bridge among radio amateurs, trying to have more of them at next year's race, and promotion for radio amateurism among the thousands of people accompanying the event, and through press and magazine publications, was the goal for this unusual initiative.

Of course runners could not worry about technical results, due to equipment care, lack of concentration at the race, and special attention to radio calls and to base-controller information, but final results were very interesting. LABRE's station PY1AA, under control of Maciel PY1ZH, joined HF calls to VHF, and many a long-distance QSO was a "WOW!" S. Paulo, Parana, and Minas States were contacted, and even an "Air Mobile" from a Boeing flying over Mato Grosso. The idea is very promising for years to come at the Races of The Bridge!

The race's scheduled time coincided with the "Patrulha Verde Amarelo" Net (Green and Yellow Patrol), a sweeping 40-meter net covering all Brazilian states, so some very interesting QSOs were realized, now and then, as PY1ZH joined 40 meters to VHF! As runners were using the PY1AA call, special interest was raised due to the possibility of QSO points for the PY1AA On-The-Air Award, sponsored by our LABRE RJ.

Well, we've read about races being described and accompanied by radio amateurs from the outside, but coming from the inside, from runners of the race themselves, it's really a first time! Special awards were presented to Paulo Roberto and Adilson—and they sure deserved it!

Adilson and Paulo Roberto near the finish line in Paris Square, Rio de Janeiro.



CYPRUS

Aris Kaponides 5B4JE

Cyprus

NEWS FROM CYPRUS

Summertime in Cyprus usually means, for local radio amateurs, fewer voices on the air. Most amateurs over here enjoy the sea or the mountains during their summer holidays and the HF rigs are set aside. However, the VHF rigs are used quite a lot from the holiday or portable locations. Most of the 2m contacts are between local hams, but some DX is also done with 4X- or OD-lands. During the first week of June, a lot of excitement was created by sporadic-E openings on 2m where a few 5B4 DXers made contact with HA-, YO-, and YU-lands. A few of the lucky ones who managed to work on sporadic-E were 5B4MC, 5B4LP, 5B4OK, 5B4MD, 5B4IT, 5B4IE, and 5B4JE.

Many interesting contacts can be made from central and western Cyprus with SVS- and SV9-lands and some of the Greek islands in the Aegean Sea. Fellows talking simplex on 2m with SVS and SV9 were 5B4JR, 5B4JX, 5B4JZ, and 5B4MG in Paphos (western Cyprus), and from the Nicosia area (central Cyprus) were 5B4OA, 5B4IE, 5B4MC, 5B4MD, 5B4LP, 5B4IT, and others.

A very interesting experiment was done successfully in Paphos by 5B4JX, who constructed a VOX system whereby he can connect the R3 repeater in Heraklion in Crete with R5 in Cyprus, or the R4 repeater in the Paphos area with R5, which is on the highest mountain peak in Cyprus. In this way, amateurs in Crete, Rhodes, Santorini, and other Greek islands in the Aegean can be linked with Cyprus. Also contacts were made with amateurs in Athens (via this system) who could open the R3 repeater in Crete. It is hoped that the system will operate on a permanent basis during the summertime. Many thanks to Sotos 5B4JX for this service on behalf of all amateurs in SV- and 5B4-land.

Recently an enthusiastic group of young men passed their radio-amateur examinations. Amongst those were some harmonics of well-known amateurs, such as the daughter of 5B4JX, YL Florentia, the son of 5B4EI, Iacovos, and my own son, George, age 16, who has the callsign 5B4OV. We are sure that all the newcomers will do well and we welcome them to the hobby.

In Cyprus there are five active club stations in Nicosia, Larnaca, Limassol, and Paphos. These are operated for 2 to 3 hours per week. From what I know, not many people are operating from there, but the club committees are trying their best to attract more young people to the club stations. An effort is made by CARS that this be a stage of practice and experience before the written radio-amateur examination. Our club stations are still very poorly equipped, and any help coming locally or from abroad will be appreciated. Please send all donations to Cyprus Amateur Radio Society, PO Box 1267, Limassol, Cyprus.

SATELLITE RS6 (RADIO SOVIET 6)

Michal OK2BXF from Brno was interested in satellites already as OL6BDK. He established the first contact via the satellite RS6 on February 12, 1984, with the transistor output of 5 Watts (the transistor exciter 200 mW and a power amplifier with QQE 03/12) and with ground plane and HB9CV antennas. The receiver antenna is a dipole and it is on the receiver input KFW16A. With such a transmitter, QRP—5 Watts ERP, he established even 5 contacts during the one orbit.

According to OK3AU, there are further new stations on the RS satellite carriers. These are the stations OK3LW and OK3WAO from the region of East Slovakia.

GREAT BRITAIN

Jeff Maynard G4EJA
10 Churchfields
Windes WA8 9RP
Cheshire
England

I was pleased to note that the recent D-Day Anniversary celebrations included a tribute to the role of the amateur in providing operating skills and development expertise in the field of radio during World War II. As you no doubt saw in the television coverage of the event, the beaches were visited by The Queen and Prince Philip.

The latter is the patron of the RSGB and was the recipient of a message of greeting originated by a D-Day special-event station, GB4DD, at the London Air Traffic Control Center, RAF, West Drayton, and sent to a French special station, FV6PAX. The received message, asking the Prince to convey greetings from all radio amateurs to the assembled Heads of State, was handed by FV6PAX to the Mayor for onward transmission to the Royal party.

Sometime later, GB4DD received a message, again via FV6PAX, from The Queen expressing thanks for the original message and wishing all the best to all radio amateurs in the nations involved. Needless to say, everyone concerned with GB4DD was delighted at the receipt of the message.

PRACTICAL WIRELESS

I will now digress somewhat from the general type of news and information that makes up the bulk of this column. This is because I have just come into possession

of three books recently published in the UK of which two are directly related to amateur radio and the third of which will be useful in most shacks. All three books are reprints of a number of articles originally published in *Practical Wireless*, the monthly UK publication dealing with all aspects of radio (and not necessarily of direct interest to active hams). The three books are titled *Wires and Waves*, *Introducing RTTY*, and *Are the Voltages Correct*?

Wires and Waves is subtitled "a guide to antennas, accessories, and propagation" and contains no less than 42 articles in 160 pages. The topics covered range from theory through antenna construction to swr bridge and other accessory construction. This is mostly a practical book, with the theory section limited to only five subjects, of which one is yagi design principles, anyway. The practical coverage of the book is aimed at the transmitting and receiving amateur alike and concentrates on the constructional aspects of low-cost antennas for HF and VHF bands. Most of the designs use readily-available and cheap materials.

Most of the antennas for construction seem to be based on much practical experience and not just theory. For example, a 2-meter beam is described for construction from a broom handle, car brake pipe, and aluminum tubing. In similar vein is the construction of a pseudo beam antenna suitable for installation on the balcony of a high-rise apartment block and based on two mobile whip antennas and an ingenious phasing arrangement.

Accessories described, in addition to the swr bridge already mentioned, include an ATU, an audible field strength meter, and a couple of preamps together with some notes on interference, suppression, and filtering. I found the low-pass SW-listener filter particularly useful and easy to reproduce.

Each constructional article includes a full list of components together with a cost estimate (in pounds sterling, but you would, no doubt, find it indicative) and a construction rating. This latter guide is Beginner, Intermediate, or Experienced. It's always nice to have an indication of cost and complexity before embarking on a project.

Wires and Waves is similar to but complementary to *The ARRL Antenna Anthology*.

I must confess an interest before describing *Introducing RTTY* because it is based largely on a series of articles of the same name which I wrote a year or two back and which were serialized in *Practical Wireless*. In addition to my articles introducing RTTY are some software and a number of equipment reviews.

My original aim was to explain the background of RTTY and follow that with a collection of modules that the reader could assemble in any suitable configuration he wished to form the basis of his RTTY station. RTTY is a form of data transmission based on Mr. Baudot's 5-unit code transmitted at 45.45 baud (60 wpm). The initial article illustrates the development of RTTY signals (from terrestrial TTY) and shows how FSK and AFSK signals are produced with modern transceivers.

Rather than describe a complete terminal unit (TU), the remaining sections describe a variety of circuit building blocks which may be put together as desired. These include, for example, interfaces between TTL and ±12 volts and single-and double-current 80 volts, filters, tone generators (including a crystal-controlled version), and various demodulators.

Using these building blocks, the reader can put together a basic TU for reception only or reception and transmission depending on his requirements. Having whetted his appetite, a more sophisticated TU will no doubt follow (personally I now use Dovetron, which is first class but expensive).

The third of the *Practical Wireless* books is subtitled "a guide to fault-finding with your multimeter" and provides 44 pages of detailed theory and practice regarding circuit-voltage measurements. Basic principles are explained from simple voltage dividers through the effects of meter resistance to the influence of inductance and capacitance in ac circuits.

The real benefit of the book, though, comes with the sections on applying a multimeter to fault-finding in real circuits. As, for example, a number of popular radio circuits are discussed with the voltages one can expect in both working and failed equipment.

The three books are obtainable directly from the publishers: IPC Magazines Ltd., Westover House, West Quay Road, Poole, Dorset BH15 1JG, England. Prices (including airmail postage) are: *Wires and Waves*—\$6.22; *Introducing RTTY*—\$2.13; and *Are the Voltages Correct?*—\$3.05.

Airmail subscriptions to *Practical Wireless* magazine are \$40.00 per annum (12 issues). All conversions are at \$1.40 to each pound sterling.

Once again I must say that although I love to hear from readers, please *do not* write to me about these books. I have no easy means of shipping them, so please contact the publishers directly.

PROPAGATION

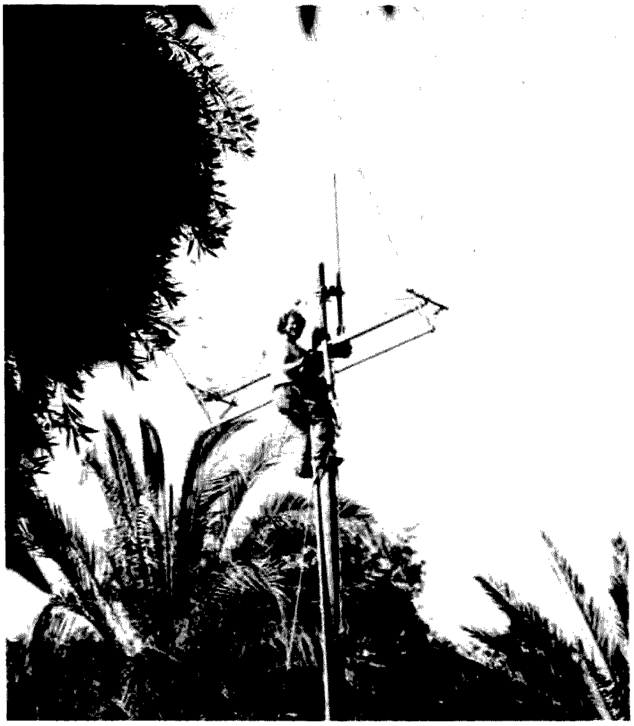
As these lines are being written, the long hot summer is upon us. VHF conditions vary from good to excellent with the typical eastern Mediterranean tropospheric ducting facilitating daily two-meter contacts between Israel and Cyprus and sometimes the Greek islands. On HF, ten meters is all but dead, but twenty meters is the star with the band wide open to North America during the late night plus long-path propagation to Australia/New Zealand in the early morning. Fifteen meters often comes alive at night with openings to North and South America, although generally to certain areas alone and not wide-open conditions.

MOUNT CARMEL RTTY REPEATER

The newest addition to the chain of repeaters in Israel, W4FQM/4X RPT, was activated in the spring. Located on Mt. Carmel overlooking the Mediterranean Sea from a height of 350 meters, this repeater is a unique phenomenon in our region presenting the amateurs with almost endless possibilities for use. It was built, shipped over, set up, and donated to the Israel Amateur Radio Club by Ed Webb W4FQM. It is a near duplicate of a machine built and operated by Ed in Florida, and the hams here are just beginning to discover its various uses.

The input frequency is 144.700, the coding frequency for radioteletype in IARU Region One. The output frequency is 145.300, making the repeater compatible with standard two-meter gear using a 600-kHz split. Mark frequency is 2125 Hz and space is 2295 Hz. To activate the repeater, you must frequency-modulate your signal with the mark frequency for two seconds, and the repeater will open, leaving a tail of 15 seconds at the end of each transmission. Should the repeater fall, you reactivate it with the mark frequency.

In the RTTY mode, the machine does not operate as a typical FM repeater. Rather, it digitally encodes the signal received and reconstitutes it with a vastly-improved signal-to-noise ratio. Thus, a RTTY signal under the noise and not clear to the human ear is turned into a clean, readable signal making possible solid long-range contacts where all else might fail.



Ron Gang 4Z4MK.

Technically speaking, the heart of the repeater is a 20-Watt Hamtronics unit with a 70-Watt amplifier, with a Wacom duplexer consisting of four cavities ahead of the antenna. At the time of writing, the repeater also functions on standard FM, although a transmission of the mark frequency will shift it over to the RTTY exclusive mode, so that the machine may be used on voice on a secondary basis. From my QTH, 200 km south of Mt. Carmel, I have succeeded under ducting conditions to make contact through the machine using an indoor hand-held rig with its rubber-duckie antenna. This testifies for the superb sensitivity of this repeater!

Lately, Israel 4X4UF has begun transmitting a nightly bulletin at 10:00 pm local time, on RTTY, of course. The bulletin is a summary of the weekly *HaGal on the Air*, IARC news magazine, edited by 4Z4RM and 4X4UF. It consists of local and international amateur news, buyers' and sellers' announcements, technical news, etc. The bulletin is updated every Wednesday, and Israel will transmit it at other times upon request.

Reportedly, Ed W4FQM is building a mailbox for the storage and retrieval of messages on the repeater. With the proliferation of home computers and amateurs using them to get on radioteletype, interest is running high. We are all grateful to Ed for his gift, and without doubt it has already made a great contribution to the technical advancement of Israeli amateurs. Amateurs in the Mediterranean basin are invited to try to work through the repeater, and it will be interesting to see what kind of DX will be possible.

OSCAR NEWS

Ya'ir 4X4GI reports that at this time there are five Israeli stations making contact through the OSCAR 10 satellite: 4X4FQ, 4X4GI, 4X4IX, 4X4MH, and 4Z4AG. Ya'ir has contacted stations in Hawaii, New Hebrides, and other "rare" islands in the Pacific through the bird, accomplishments normally quite difficult from here on the HF bands.

Steve 4X6MF, who by the time you are reading this should be active on the satellite along with the other new Israeli stations, is beginning to organize a local chapter of AMSAT. Reports are that there are more satellites in the offing, and with the decreasing sunspots and poorer HF conditions, interest is mounting in the country in satellite communications.

INTERFERENCE ON TWO METERS

It is a well-known fact that the two-meter transceivers manufactured for amateurs sell for a fraction of the price of sets produced for the commercial two-way radio market. For this reason, many clandestine organizations around the world use amateur gear for their nefarious purposes, and certain dealers are more than happy at this opportunity to turn a profit, no questions asked.

For many years, until the PLO terrorists were expelled from Southern Lebanon in June, 1982, two meters in Northern Israel especially was plagued by interference from these quasi-military groups. Especially hard hit was the Haifa repeater, with its input frequency of 145.000 MHz apparently being a calling frequency for these outfits. As a result, a tone access was added to the repeater to prevent its being triggered by non-amateur signals. This feature was deleted after the 1982 war silenced the source of this QRM.

Two-meter non-amateur activity is

again on the rise in Lebanon by the various organizations operating there. Now with the summer upon us and long-range tropospheric propagation present, these stations are being heard all across the two-meter band. This time, strangely enough, the main victims are the repeaters in Cyprus, especially on R2 and R5. At some times of the day, say our Cypriot counterparts, these repeaters become virtually unusable because of the clandestine operations on their input frequencies.

This time, no immediate solution is in sight. This curiosity is simply one of the by-products of political instablity in our area, and we'll have to learn to live with it.

Republic of Liberia

CB NO PROBLEM IN LIBERIA

Our amateurs are aware of the evils associated with CB radio and are determined that it will not get out of hand here. It is legal, but at the present time a CB license is very difficult to obtain. There are those who want to get on the air without doing all the work of learning the code or of passing theory tests. They are working at it here as they are in the US and other places. To date they are losing the battle.

In the commercial broadcast band there is a lot of empty space. We have only three stations. One is really commercial and the other two are mission stations which are commercially licensed but which exist primarily to bring the good news of the gospel to the people they can reach. With all this empty airspace, the Liberia Radio Amateur Association has the bright idea of obtaining a spot on which to broadcast code much as is done by W1AW. It is not practical to do that on the amateur bands because so many of the people for whom this service is intended do not have and will not easily get an amateur radio. The Association has been working on this idea for more than a year. Things move slowly in Liberia.

In Holland, there is a great problem of unlicensed broadcasting to and for the general public on the regular commercial bands. The problem is completely out of control, much as is CB in the States. Some of our outlying mission stations are looking at that situation with interest. In one case it has gone beyond the looking stage and there is a five- or ten-Watt stereo station in operation. Everyone is happy. The station operates three or four hours a day with music and news reports and is the only thing that is available to that community. This little station, though not formally licensed, operates with the knowledge and consent of the Ministry of Telecommunications.

Another mission station is considering the possibility of a like operation. This is very interesting, and from where we sit it seems that there is nothing to lose and everything to gain. Certainly the people in those outlying communities appreciate what is being done. It is a credit to the Ministry that they do make an exception in this instance, and so long as these little outpost stations operate with proper authorization, there is little likelihood that things will get out of control.

That is a little aside. The immediate problem is that everyone wants to take a shortcut into the world of amateur radio. "No-code licensing," CB space in the amateur bands, just anything to get in without doing the work. Over and over again we find that the results are counter-productive. Japan has no-code licensing. For an evaluation of the result read *73*, August, 1983, page 73. The amateurs must be alert and they must make every effort to preserve the great hobby that is theirs. In the States they have won another round, and that is all that it is—another round. See *73*, March, 1984, page 104. When the amateurs give in or simply lose the fight, amateur radio as we know it will just fade away.

In Liberia, the Radio Amateur Association works very closely with the Ministry of Post and Telecommunications, which is the department of government under whose jurisdiction amateur radio operates. The Ministry scans the amateur bands and checks for violators. The amateurs themselves do the same in a somewhat less organized but nonetheless effective way.

Amateurs in Liberia do follow the rules and they take pride in maintaining a high standard of courtesy and technical efficiency. The same can be said of most of the amateurs of the world, but not all. I, as an outsider living in Liberia, am impressed. I think it is a great credit to this little country, and as amateurs around the world make their contacts with Liberia, they will meet with courtesy and respect.

SCANNING FROM MARS

Well it's the official Annual Hurricane Season once more in the Caribbean area. This comes into effect on June 1st each year, and with 22 hurricane names listed for this season, it's small wonder that amateur-radio operators throughout the region are keeping a watchful eye on weather conditions as a measure of disaster preparedness.

The island of Montserrat, a British colony located in the eastern Caribbean about 268 miles southeast of Puerto Rico and only 39-1/2 miles square, has just held a three-day Disaster Preparedness and Emergency Management Workshop. This was jointly sponsored by the Pan-Caribbean Disaster Preparedness and Prevention Project Committee (PCDPPP) and the government of Montserrat, which was designed to correlate plans and actions to be taken by the various groups and organizations that are usually involved in the education and protection of the general public in times of national emergencies and disasters.

This workshop was held at the Government Training Center located in Plymouth, the capital, beginning on Wednesday, June 20, and ending on Friday, June 22. Lecturers were Mr. Jerome Lloyd—Consultant, PCDPPP, Dr. Deryck W. Heinemann—Project Manager, PCDPPP, Lt. Col. Glenn A. Mignon—Disaster Preparedness Advisor (UNDRO), PCDPPP Course Director, and Miss Elizabeth Twinch—British Red Cross Advisor, PCDPPP.

The workshop was attended by senior officials of the Executive Committee (Disaster), officials of government, statutory boards and companies, and voluntary organizations, also district and deputy chairmen. Some of the topics discussed at the workshop were:

- Preparing the community for disasters
- Role of the security forces in a disaster
- Role of the Red Cross during these times
- Role of communications, with a presentation given by the president of the Montserrat Amateur Radio Society, and role of the media
- Role and functions of the disaster management organizations
- Managing mass casualties

Many other aspects of disaster and emergency preparedness were covered, all of which incorporated the use of radio communications for efficiency because of the terrain of the island. Thus the Montserrat Amateur Radio Society plays a vital role as the organization most readily equipped to provide this service.

As previously stated (see *73*, May, 1984), the Montserrat Amateur Radio Society has a team of operators assigned the task of manning various police stations, the airport, the hospital, and the local government public broadcasting station (ZJB), thereby providing a continuous link with the Central Control which is located within the confines of the Plymouth Police Headquarters.

In addition to these stations, which will be operating via the 2-meter repeater (but with capabilities of reliable simplex operation), there are at least two additional stations delegated to operate on the HF bands with the objective of maintaining contact with the outside world in the event that all other means of communications become unavailable.

These stations are readily equipped with standby generators, batteries, dipoles, and verticals should the main antennas be lost in the expected gale-force winds usual with hurricanes. These are the stations of Dr. Konrad Hollatz VP2MF and VP2MO; the latter will be operated by Mae Martin VP2MN. Both these stations were very active during the 1979 Dominica crisis caused by Hurricane David and provided the necessary information to one of our local radio stations (Radio Antilles, a 200,000-Watt system that covers the entire Caribbean Area and beyond) and the Government Broadcast Station which covers the neighboring islands.

At this time, as has been the practice of the past years, all members of the Montserrat Amateur Radio Society's Disaster Team are maintaining a close link with each other just in case...

On the HF band, the designated standby, weather watch, and coordinating frequencies for the Caribbean area are the same as those of the Antilles Emergency and Weather Net. These frequencies are 3.815 MHz in the evenings and mornings and 7.168 MHz during the day.

This net operates twice daily, 365 days a year at 1030Z and 2230Z, normally on 3.815 MHz, and reverts to the 40-meter band only for exercises or in times of disasters. During normal nonemergency times, the net operates as follows.

Two islands are responsible to provide NCOs on a weekly rotational basis, one island doing the morning session and the other the evening session. There is a roll call for island-by-island check-ins, beginning with Venezuela in the far south to Jamaica and beyond in the north.

Weather information is provided from the Netheriand Antilles, Trinidad and Tobago, Barbados, the French Antilles, Antigua and Barbuda, and The US Virgin Islands, obtained from their respective net offices, thus providing a concise weather picture throughout the Caribbean area.

The Montserrat Amateur Radio Society recently met for its annual general meeting, during which the following officers were elected for a term of one year. President: Errol "Bobbie" Martin VP2MO, Vice-president: Sydney St. C. Meade VP2MC, Secretary/Treasurer: Mrs. Ursula Sadler VP2MDY, Equipment Officer: Victor James VP2MQ, Activities Manager: Tony Glaser VP2MIX, and Executive Member-at-Large: Dr. Vernon Buffonge VP2MV.

The following persons have been reappointed to these respective positions: Awards Manager: Errol "Bobbie" Martin VP2MO, and QSL Manager: Mr. Gene Ege, Sr. WB2LCH.

Please note that Gene WB2LCH is QSL Manager for these stations on Montserrat *only*: VP2M (Special Events Station), VP2MN (Joanna "Mae" Martin), VP2MO (Errol "Bobbie" Martin), and VP2MLD (Lawton Daley). All other QSL cards should be sent to their respective owners and *not* to WB2LCH.

QSL PROBLEMS

One of the major problems that the Society (*and* VP2MO) is faced with is that of being used as a QSL Bureau, and as such we are being clobbered with cards from all over the globe. The strangest part of it is the fact that cards are coming here for countries as far away as J20 and the rest of the Caribbean area.

Please be informed that no QSL Bureau exists on Montserrat, for we are not equipped to handle this service—neither financially or otherwise. This matter is ofttimes discussed at our club meetings, and the only persons being catered to by the Society are its members and others who have made the proper arrangements with the Society. Please also note that the more active *resident operators* here each have a QSL Manager, and anyone needing a response should utilize the managers' services as much as possible, unless the operator states otherwise. This method would make things much better for all concerned.

Guest operators usually give their respective QSL route, and one has only to listen. Another situation which exists and needs to be rectified is the direct QSLer. These fall into three basic categories: (1) An enclosed SAE with return postage, (2) An enclosed SAE with no enclosed postage (sometimes no enclosed envelope), and (3) a QSL card, stamped, mailed with a request *PSE QSL TNX*.

My response to these types are as follows:

The first person does the proper thing, for even if the enclosed postage is inadequate, he deserves an immediate response with a card via first-class mail.

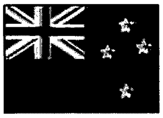
The second type of person has got to realize that the DX station must have worked many stations, thus if he were to send a card to everyone without the necessary postage, he would not be able to stay on the air for very long, and even were he to be able to respond to 50%, who would deserve to be that lucky half?

Regarding type 3, I think that anyone who would pay (?) to have his cards printed and then just throw them into the mails caring nothing about defacing his callsign and any other info that was so carefully put together doesn't deserve one of mine, for to me a QSL card represents something, so I think that that kind of person has no respect for his card, his call, nor the operator at the other end, for why do they make envelopes anyway? Proud of your call? Proud of your card? Then prove it!

Until we meet again, my fellow hams

out there, it's always very pleasant to meet operators (VP2MO) saying catch me on RTTY daily from about 1700Z on or near 14.084 MHz, and if you're lucky you might even run into Joe VP2MJL or Tony VP2MIX, and very soon, too, "Doc" VP2MF.

73 and gud DX as I'll be scanning from MARS.



NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

This month I shall give readers a couple of examples of the close liaison between the ZL regulatory body, the New Zealand Post Office, and NZART, our amateur-radio national association.

In 1982, the NZPO decided to conduct a review of the Amateur Service as a whole in view of changes it had observed in other countries and because of submissions from NZART. The last major change to the Amateur Service was in the mid-60s when the Grade III Technician class was introduced. Since that date only minor changes have been introduced with the introduction of the New Zealand Radio Regulations 1970 (an update on the previous radio regulations).

Accordingly, NZART was invited to put forward submissions for a review of the Amateur Service as a whole which could be considered in conjunction with changes the Post Office itself saw as being advantageous. Generally, the proposals submitted had to conform with the conditions laid down by the International Radio Regulations.

In response to the invitation, our association, after several top-level discussions, submitted a 37-page document, and some discussion on the proposals took place between the Post Office and a team of NZART council members.

The Post Office then drew up a paper on the outline of a proposed structure for the Amateur Service in ZL, which included a number of proposals from remits placed before the Post Office by NZART from annual conferences over a period of time. This "paper" was then distributed to all ZL licensed amateur operators, who were given the opportunity to comment on the proposals before the regulations were amended or changed to give effect to any or all of proposed changes. At the same time, the Post Office asked all amateurs for suggestions other than those put forward in the paper, provided such suggestions conformed with the general parameters for the Amateur Service as laid down in the International Radio Regulations.

It is the intent of the Post Office that, within those constraints, the conditions under which the Amateur Service in New Zealand operates reflect the wishes of the majority of the users. It is interesting to note here that the submissions were made by NZART on behalf of its members as the "voice" for the Amateur Service in ZL, but the Post Office saw fit to circularize ALL amateurs and allow them to individually suggest changes, thus providing for the 27% of licensed amateurs who are not association members to be heard on this important subject.

A summary of the proposals follows; readers are reminded that the changes are only suggested at this stage, but as they are the result of joint consultation, it is probable the final draft will be very similar to the following.

Qualifications: 3 levels of qualified operators: Novice, Non-Morse, and General. (The titles are merely descriptive at this stage.)

Entry may be made at any one of the levels, and the Novice grade will be non-terminating. It will be possible to hold both the Novice grade and Non-Morse grade of qualification simultaneously.

The Non-Morse grade is unchanged from the present Grade III, and the General grade will replace the existing Grade II and Grade I certificates.

Examinations: Examinations will be held twice yearly and will consist of a written examination in two parts, a technical paper and a regulations and procedures paper. (Basically the same as at present.) The Morse test will remain an essential part of the Novice and General qualification examinations, the scope of the test being widened to include a knowledge of figures and common punctuation marks. It will be possible to obtain a partial pass, but credits for part passes will remain valid only for two further scheduled examination dates.

Privileges: The General qualification will attract the privileges currently granted to the holders of Grade I certificates, e.g., all bands, all modes. The Non-Morse qualification will have the same privileges as are currently available to Grade III certificate holders, e.g., 27.12 MHz, 51-53 MHz, and all bands above 144 MHz.

The Novice qualification will be non-terminating, i.e., it may be held indefinitely without a need to upgrade, and will carry the following special conditions and frequencies: Power restricted to 10 Watts dc input to the final rf stage, and operations restricted to CW and AM (including SSB) in the bands 3525-3575 kHz and 21100-21200 kHz.

Log keeping: Consideration will be given to waive the requirement that amateur operators keep a station log in accordance with regulation 53. However, amateurs will be encouraged to keep a log, recognizing that the document plays an important part in some amateur activities.

These proposals were sent to all amateurs in ZL in April this year, and we had until May 31st to forward our submissions to the Post Office. On that date, several hundred amateurs had taken the opportunity to reply to the Post Office on the paper, and to this date there have not been many objections to the document, in the main. We now await the decision of our regulatory body with interest.

The second example of cooperation and liaison resulted from two remits passed at our recent annual conference in early June this year. In just under one month from the date of the passing of the resolutions, the Post Office implemented both proposals. They concern visiting amateurs and our Grade III certificate holders.

The ZLØ visitors' call holders will not have to suffix their ZLØ call with their home callsign as was required previously; now visiting hams will not have such an awful mouthful to say when working on the bands here in ZL, they will merely use their allotted ZLØ callsign. The other remit requested the Post Office to permit Grade III operators to use CW on their allotted frequencies. Previously, Grade III could not use the CW mode but were permitted to use all other modes.

BITS 'N' PIECES

Silent Keys recorded recently were D. (Dan) McMahon, ex ZL1CM, aged 88 years, a respected, retired Auckland Radio Inspector and long-time amateur and marine operator; and M. H. (Mark) Churton ZL1TB, another old-timer and well-respected amateur operator well-known to many overseas hams.

Old-Timers Club 50-year certificates were recently presented to R. A. (Ray) Anderson ZL3JV and T. E. (Tom) Rowlands ZL3JX, and 60-year certificates went to T. R. (Tom) Clarkson ZL2AZ, ex ZL2AR and ZL1FO, and H. N. (Nev) Shrimpton ZL2AUM, ex ZL4AO and ZL2BJ. Congratulations to these operators for their long and active career in amateur radio.

Over recent columns I have been reporting on ZL offshore islands and their respective amateur activities. This month I shall briefly tell you about another ZL offshore island, but unfortunately the amateur activity would not have been of any use to overseas amateurs as the operator was confined to VHF activities.

Snares Islands, a small group of uninhabited islands 209 km southwest of Bluff (the southernmost port of ZL) at 48°S 166°36'E, were discovered independently on the same day, November 23, 1791, by Vancouver in the *Discovery*, and Broughton in the *Chatham*. The group covers an area of approximately 350 hectares and consists of coarse granite with a covering of peaty soil. The soil is densely vegetated, mainly by tupari (Olearia iyallii), which creates an almost closed canopy to 6 meters high.

The Snares Islands are administered as a nature reserve under the Reserves Act by the Lands and Survey Dept., and entry is by permit only. This is due to the absence of introduced mammals and virtually unchanged vegetation and animal life. Their pristine state gives these islands world recognition as important sanctuaries.

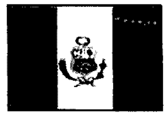
During the three-month period December, 1983, to February, 1984, P. J. Wilson ZL3TJD/A, ZL9TJD operated an amateur station on VHF from Snares Island. He operated on 2 and 6m with an Icom 260A into a 10-element yagi, and an Icom 505 into a 5-element yagi. Both rigs were powered by gel batteries, charged using a Honda generator.

Contacts on 6 during the three-month period included VKs 1, 2, 3, 5, and 7, and ZLs 1, 2, and 3, and ZL7OY; Chathams was heard, but unfortunately not worked; 2m contacts through repeaters at Invercargill and Queenstown were made as were five simplex contacts with ZL4 stations from the high part of the island, Signpost Hill, 82m above sea level.

The trip to Snares Islands was made by a University of Canterbury field party, ZL3TJD being employed as a technician to assist with the penguin census and banding, as well as with some entomological collecting. The visit was made possible through a research grant provided by the Lands and Survey Department. (Information for this item was supplied through the courtesy of *Break-In*, the NZART monthly official journal.)

The 24-GHz record for ZLs was broken on April 7, 1984, when Tony ZL1BHX and Russell ZL1BQK extended the communication distance to 33 km, in the Ninety Mile Beach area in the North Auckland area. They used 25-mW Gunplexers™ into 17-dB gain horns and 30-MHz homebrew (DJ7OO-designed) i-fs. Their report states the first contact was from Ahipara Lookout to Hakatere Forestry Observation Post. Then once they had established contact, Tony ZL1BHX moved up the beach, but after the distance was extended further, the salt-spray haze increased and copy was in and out quite rapidly, so they decided to quit while still ahead of the old record.

A "contest with a difference" is held annually in ZL that always causes a lot of laughs—it is the QLF activity, this year held on Wednesday, August 15, 0800Z to 1000Z. Its main object was to have a packet of fun on 80 meters. The rules are very simple, the execution a little difficult for some. The mode is CW, a straight hand key must be used, and operators use the hand not normally used, e.g., right-handed ops use their left hand and vice versa. If by chance you're ambidextrous, you must operate the key with your foot. Scoring is one point for each contact, with a bonus of one extra point for each contact where either operator is using "foot keying." In the case where both operators use foot keying, they score three points each for the contact. There's no prize, but the contestants submit their own score sheets and a winner is declared for this fun activity.



PERU

Luis E. Suarez OA4KO/YV5
Apartado 66994
Caracas 1061-A
Venezuela

I have resided in Venezuela since 1973 and have written several columns here about that country, but as a Peruvian I miss the flag of my own country in "*73 International*" and that's the reason I'm now at my computer, writing about amateur radio in Peru. I hope that somebody down there in OA-land feels motivated to become a correspondent for "*73 International*."

I wish you readers to know that I have little material since I left my country 11 years ago, and certainly many things must be quite different. I have tried to get some news but really have not received much. In fact, it is very difficult to receive support from readers and from radio clubs, no matter their whereabouts. People like to see their names printed and club members are delighted to see their clubs' activities published, but when you try to get information for publishing everybody says "I'll call you . . . !" Actually, nobody calls you back. The same with requesting pictures or any printed material.

Peru, the land of the Incas, is located in South America facing the Pacific Ocean, between Ecuador and Chile. The territory has four natural regions: the Coast, the Sierra (Andes), the Selva (jungle), and the fourth, which is the territorial sea that extends 200 miles from the coast. The Coasta is almost only a strip of sandy land (almost never rains) but it has 23 valleys, one for each river, where most coastal cities are located.

The Sierra is all the central region crossed by the Andes from north to south. In this territory is located the highest railroad and one of the highest cities of the world. Here also is located the highest lake in the world (Titicaca) and also the third highest mountain in the Americas.

Peru, for communications purposes, is divided in 9 zones (call areas) as shown on the map. I remember that the OAØ prefix was for maritime mobiles, but now the *Radio Amateur Callbook* lists several Peruvian warships with the OA4 prefix and the designation, Radio Club Naval BAP (ship name). I don't know the reason for this. There are no inhabited islands in the Peruvian sea, except those with navy installations. Thus I assume that the OAØ prefix should still be devoted to maritime mobiles.

Radio-amateur licenses are of three

A Tree-Mendous Vertical

Build an 80m DX-getter that really grows on you.

Eighty meters is a fun band. Something for everyone is the byword. From the diverse nets entangling the top end, through the casual groups and rag-chews in the spectrum, to the well-populated CW band, you are challenged not to find an entertaining operation. DX, especially in the winter months, is surprisingly good. With the sunspot cycle approaching its minimum, we'll see it get even better.

For you uninitiated, tune through the 3790–3800-kHz DX window some evening from sunset until a few hours after. For the most part, I guarantee you'll hear stateside stations working DX. What I can't guarantee, with your 30-foot-high loaded dipole or ground-mounted trap vertical working against 3 radials, is whether you'll hear the DX stations.

80 meters is no different in its antenna requirements than the other HF bands. A dipole or inverted-V hung a half-wave above ground is a good performer, as is a quarter-wave vertical working against a good ground system. The only problem is that a half-wave at 3.8 MHz is over 120 feet. The opportunity to construct such antennas eludes most of us because of space restrictions or lack of green stamps to buy and plant large support structures. A forty-foot-high inverted-V might bag WAS on the 3787-kHz GERATOL net during a winter season, but it lacks the zing needed for DX competitiveness.

All is not lost! Described here is a low-angle radiator that anyone with a 40-foot-high tree in the vicinity of the ham shack can construct and use to gain that competitiveness on 80 meters.

Design of this antenna is an adaptation of the folded umbrella described by John Haerle WB5IIR.[1] I suggest you obtain John's article for further information on this superior design. Construction is simple, straightforward, and noncritical. No ground radials, base insulators, loading coils, or high-cost items are required. Approximately 100 feet of small nylon line, some assorted TV hardware, a few ground rods, and four 90-foot lengths of any wire are all that's required. I recommend no. 14 insulated house wire, but I've used no. 17 galvanized-steel electric-fence wire in one installation.

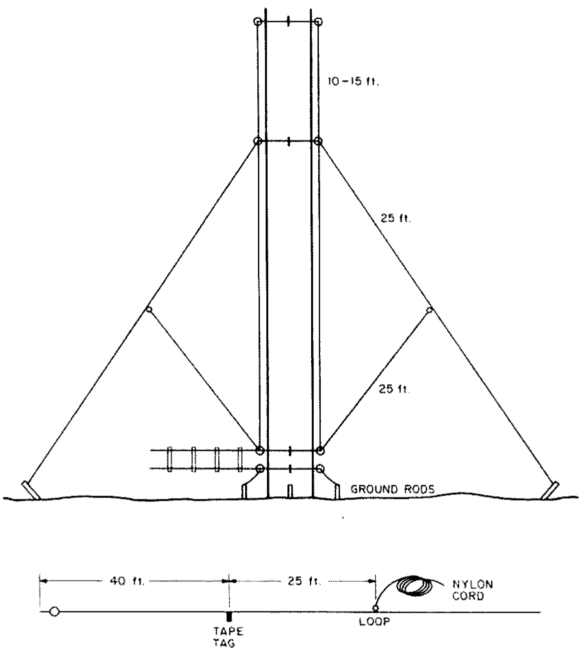

Fig. 1.

Observing Fig. 1, you can see the idea is to cage the tree with wire. I use 4 wires, but I have the feeling more vertical wires along the trunk would be an improvement. Sure, I know. Everyone says trees are great rf absorbers, but I'll say this antenna plays as well as John's folded umbrella in my backyard.

Attach four TV-standoff eyes at equal spacing around the base of the tree about a foot off the ground. Form a loop of wire through the eyes. Hammer in ground stakes by each eye and connect wire to the stake and loop by soldering or using small Servit™ connectors. This completes the ground system! A few radials will help if you have the room but are not necessary.

Place four more eyes into the tree an inch or two above the ground-ring eyes. Form a wire loop through these eyes. Roughly measure 90 feet of wire and attach an end to one of the eyes. Measure 40 feet from the eye and tag the wire with some tape. Measure 25 more feet and twist a loop

in the wire. Attach about 30 feet of nylon cord to the loop. This is shown in Fig. 1. Now climb the tree with the loose end of the wire, making sure it lays close along the trunk. When you reach the tag height, screw in four more eyes. Again, form a loop of wire through them. Thread the loose end of the wire through one eye and throw the remaining wire and nylon cord out through the branches. A weight will help. Bring up three more wires using the respective eyes. I did these one at a time to keep them from tangling. The branches of my oak tree were enough to contend with!

At the top standoff eyes, attach a 10- to 15-foot wire to each. Either continue up the tree with them to another eye and wire-loop arrangement, or if you've run out of tree, lay them out on limbs to form a semblance of a top hat.

When you're back on the ground, pull the four loose wire ends in to the tree trunk and connect them to their respective eyes as shown in Fig. 1. All connections should be soldered or connected with Servits.

Open-wire feed from an unbalanced matchbox will net you all bands from 160 through 10 meters. If you desire coax feed, you might have to adjust the top-hat length to resonate the antenna to your preferred 80-meter frequency, although you'll find it's quite broadbanded.

Now try 3790–3800 kHz some evening and enjoy *working* DX. I know it doesn't outperform W1CF's phased array, but then I haven't wired the other three trees! ■

When Darkness Calls

On 160m, success means diligent planning. These tips on gray-line propagation are your key to Top-Band DXCC.

Anyone who works Top Band knows that strange and wonderful things happen around sunset and sunrise (twilight at your end of the QSO, at the other end, or at both). There are some interesting reasons for this, and if you have a better understanding of what causes the DX to emerge at these special times, you have a head start in the drive for WAC or DXCC 160.

"Sunrise" in this context may last quite a while, from sometime before the sun actually appears until sometime after it has cleared the horizon. The duration of the effect depends on the latitude of the location and the time of year. For example, in midwinter at the equator the time window is very narrow, about ±5 minutes; at 50° about ±45 minutes; at 60° about ±90 minutes. If you have watched the sun rise in the tropics, you will have noticed that it rises almost due east and zooms straight up into the sky very quickly. In polar regions it creeps out of the SSE horizon and travels almost horizontally, so it is not easy to decide just when it has actually arrived.

Finding the Times of Sunrise and Sunset

There is no problem in knowing when to expect your own sunrise and sunset, but how can you find the times for a particular DX location? Here are some of the ways:

1) The "DX Edge" is a slide-rule-type operating aid made especially for this purpose and has information on zones, prefixes, etc., as well. It is simple to use and is available for $14.95 postpaid from: The DX Edge, PO Box 384, Madison Square Station, New York NY 10159.

$$\text{Sunrise} = \frac{\text{longitude W}}{15} + \frac{\cos^{-1}(\tan a \times \tan \text{latitude N})}{15}$$

$$\text{Sunset} = \frac{\text{longitude W}}{15} - \frac{\cos^{-1}(\tan a \times \tan \text{latitude N})}{15}$$

Fig. 1. Formulas to calculate sunrise and sunset in decimal UTC where "a" is the inclination of Earth's axis with respect to the direction of the sun at that particular time of year.

2) If you have a calculator which handles trigonometric functions (and you know how to use it), the times can be calculated using the formulas in Fig. 1. To use these formulas you have to know the inclination of Earth's axis with respect to the direction of the sun at that particular time of year. John Devoldere ON4UN has a table showing this in his book, *80-Meter DXing*, and can also supply a computer printout of times by prefix. An inclination table can also be found in K6UA's "Gray Line" article in CQ, September, 1975, p. 30.

3) If you have a Commodore computer, you can buy a collection of programs (which includes an excellent sunrise/sunset program by David Williams) for only $10.00 from Public Domain, 5025 Rangeline Road, West Milton OH 45383. If you own a Commodore 64, ask for Collection #4 and you'll get 37 other programs as well for your ten bucks—can't beat 25¢ a program! You enter the latitude and longitude of the location and the date; if you wish, it will automatically convert to UTC (GMT for the old-fashioned or Zulu for some). The computer also asks for the angle of the sun over the horizon. I enter 0°. The author of the program put in −.75° as "a widely-used figure." It makes only a few minutes difference in the calculation, but if anyone out there in *73*-land knows what this is all about, write a letter to *73* and let the rest of us know.

4) Finally, you can use Fig. 2, which is taken from a *CCIR Report* and is good for anywhere in the world at any time of the year. The time scale is in local standard time, so use the longitude of the station concerned to convert to Universal Time.

On the month axis, estimate the position of the specific day on the scale. This is very important in spring and fall; for example, you will see from the chart that at 50°S on the 1st of February, sunrise is about 4:40, but by the end of the month it is 5:25.

The Gray Line

The great circle line around Earth dividing the dark side and the sunlit side of the planet is called the "terminator." It is not a very

sharp division except near the equator, and radio amateurs call it the gray line, a descriptor brought into radio terminology by K6UA.

On the daylight side of Earth, the D-layer of the ionosphere is heavily ionized and absorbs most of the 160- and 80-meter signals, preventing them from reaching the reflecting layers above. At night the D-layer has decayed and these signals can easily go through to the upper layers and be reflected down to more distant locations.

At the terminator, a special condition exists. Fig. 3 shows the conditions in the ionosphere which help the DXer at the eastern end of the darkness path at sunrise (European working into W, or W working into JA, for example).

Ionization builds up first in the upper layers, and in fact, never entirely disappears from them in the middle of the night. At twilight the D-layer is only partially ionized: too little to absorb the 160-meter signal, and too much to allow the signal to pass straight through to the upper layer and be reflected down to medium distances (as it does during the night).

The partial ionization causes the signal to be *refracted* (bent) in the D-layer, and it may travel hundreds or thousands of miles within the layer before going on its way to the upper layer. Not only does it go further before hitting that layer, but it also arrives at a narrower angle, making for both better reflection and a longer hop.

You can see that for a station right near the terminator, an antenna with a high-angle vertical takeoff lobe may sometimes reach out further than one with an antenna which concentrates the signal closer to the horizon, but the low-angle antenna will stay in contact for a longer period after sunrise.

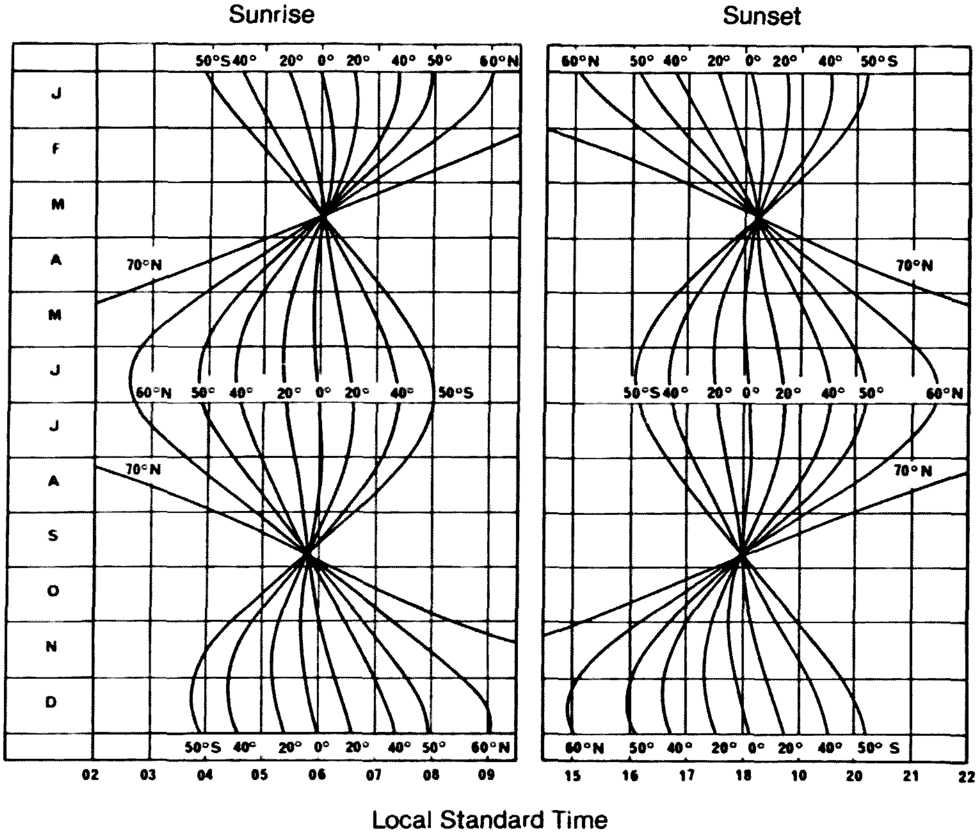

Fig. 2. Times of sunrise and sunset anywhere in the world (in local standard time).

There is another phenomenon which helps the Top Bander at sunrise. On the dark side of Earth, the F-layer is higher than it is on the sunlit side. At the terminator, where the transition from one height to the other occurs, the layer is *tilted* and signals reflected from it come down at a more useful angle for DX working. Fig. 3 illustrates this effect, which was explained in 1979 by Hortenbach and Rogler.[3]

So what do we do about it?

- At *your* sunrise, look for signals from the west of you.
- At your sunset, look for signals from the south and southeast (along the terminator) and then from the east.
- If you are in darkness, look for signals from the east at the distant station's *sunrise* or before it.
- If both you and the distant station are on the edge of the darkness path, there is an especially good chance of propagation between you. ■

KALAMAZOO MI
OCT 28

The 2nd annual hamfest/electronic flea market will be held on October 28, 1984, from 9:00 am to 4:00 pm, at the Kalamazoo County Fairgrounds, Kalamazoo MI. Admission is $2.00 in advance and $2.50 at the door. Four-foot table spaces and table rentals are $2.50 in advance and $3.00 at the door (spaces with power must be reserved and paid for in advance). There are 400 spaces available and dealer setup is at 8:30 am. For more information, contact Ham 10 FM Club of Kazoo, Ken Losey KA8RUA, 2825 Lake Street, Kalamazoo MI 49001.

FRAMINGHAM MA
OCT 28

The Framingham Amateur Radio Association, Inc., will hold its annual fall flea market on Sunday, October 28, 1984, beginning at 10:00 am, in the Framingham Civic League Building, 214 Concord Street (Rte. 126), downtown Framingham. Admission is $2.00 and tables are $10.00 (preregistration is required). Seller setups begin at 8:30 am. Radio and computer gear will be featured and food will be available. Talk-in on .75/.15 and .52. For more information, contact Jon Weiner K1VVC, 52 Overlook Drive, Framingham MA 01701, or phone (617)-877-7166.

ALBUQUERQUE NM
NOV 3

The UNM ARC and the Westside ARC will jointly sponsor a tailgate swapfest on November 3, 1984, from 10:00 am to 2:00 pm MST, on the UNM North Campus parking lot, corner of University Boulevard and Tucker Avenue, Albuquerque NM. Admission is free; bring your own tables as none will be furnished. Talk-in on 147.75/147.15 MHz and 449.3/444.3 repeaters. For further information, send an SASE to Gary Bonebrake K8BI, 974 Arkansas SE, Rio Rancho NM 87124, Robert Scupp WB5YYX, 648 Marquis Drive NE, Albuquerque NM 87123, or Jay Miller WA5WHN, 4613 Jupiter NW, Albuquerque NM 87107, or via 3.939 MHz, 0100 UTC daily.

WEST MONROE LA
NOV 10

The Twin City Hams will sponsor an all-indoor hamfest on Saturday, November 10, 1984, from 9:00 am to 3:00 pm, at the Convention Center, N. 7th Street, West Monroe LA. Features will include exams, swap tables, new-equipment dealers, and a ladies' program. Talk-in on 146.25/.85. For more information, contact Benson Scott AE5V, 107 Contempo, West Monroe LA 71291.

NEWMARKET ONT CAN
NOV 10

The York Region ARC will present the 8th annual Newmarket Flea Market on Saturday, November 10, 1984, beginning at 0800, at the Newmarket Community

Center, Civic Drive, Newmarket (just north of Toronto). Admission is $2.00 per person and children under 12 will be admitted free. Table rentals are $3.00 each plus general admission and will be held only until 0800 unless payment is made in advance (setup is at 0630). Refreshments will be available. For table reservations (include a check or money order made out to the York Region ARC) or more information, contact Geoffrey Smith VE3KCE, 7 Johnson Road, Aurora, Ont., Canada L4G 2A3, or phone (416)-727-6672 (evenings).

NORTH HAVEN CT
NOV 11

The Southcentral Connecticut Amateur Radio Association (SCARA) will hold its 5th annual Electronics Show and Flea Market on Sunday, November 11, 1984, from 9:00 am to 3:00 pm, at the North Haven Recreation Center, Linsley Street, North Haven CT. Admission is $1.50 and children under 12 accompanied by an adult will be admitted free. Tables are $10.00 in advance for the main hall and $12.00 at the door. (Reservations are strongly advised.) Setup will be at 8:00 am, and for new equipment vendors, a special exhibit area with setup security arrangements will be made available. There will be food both at the food booth and from a mobile cart. Features will include the latest in ham radio, computers, and electronics. Talk-in on 146.01/146.61 (W1GB). For more information, directions, and reservations (make checks payable to SCARA), send an SASE to Tony Vanacore AK1O, PO Box 81, North Haven CT 06473, or phone (203)-484-4175 (home) or (203)-239-5321, extension 311 (days).

PENANG, MALAYSIA
NOV 16-18

The Malaysian Amateur Radio Transmitters Society (MARTS) will host the 14th SEANET Convention on Friday, Saturday, and Sunday, November 16-18, 1984, at the Eastern and Oriental Hotel, Penang, Malaysia. Features will include symposiums, luncheons, tours, and rag-chewing. For more details, contact Malcolm Westwood, Organizing Secretary, SEANET, PO Box 13, Penang, West Malaysia.

GREENSBORO NC
NOV 24-25

The 4th annual Greater Greensboro Hamfest will be held on November 24-25, 1984, from 9:00 am to 5:00 pm, at the National Guard Armory, 1100 Franklin Boulevard, Greensboro NC. For advance tickets, send an SASE to Fred Redmon N4GGD, 2305 Sherwood Street, Greensboro NC 27403. For dealers' space, tables, and flea market information, contact Coy Hennis WD4NHL at (919)-294-2841.

OAK PARK MI
NOV 25

The Oak Park High School Electronics Club will hold its 15th annual Swap N Shop on Thanksgiving Sunday, November 25, 1984, from 8:00 am to 4:00 pm, at the Oak Park High School, Oak Park MI. The doors will open at 6:00 am. Admission is $2.00 and 8-foot tables are $6.00. Refreshments will be available. For more information, send an SASE to Herman Gardner, Oak Park High School, 13701 Oak Park Boulevard, Oak Park MI 48237, or phone (313)-968-2675.

HAM HELP

I need a VLF receiving converter similar to the now-discontinued MFJ-332. Its input should be 1 MHz and below, and its output should be on one of the HF ham bands, preferably 10 meters. I will buy a used MFJ-332, a kit, a circuit, or any other equipment.

Roger Coppock
2800 South 10th Ave.
Broadview IL 60153

Would someone please help me find a schematic or manual for a Communications Power, Inc., model WM-1000 wattmeter? I will gladly pay for any costs incurred.

Richard Whipkey AD6X
866 Yolo Way
Livermore CA 94550

Wanted: microwave X-band diodes. All types: detector, Schottky, and Gunn. I can evaluate unknown or unmarked diodes. Also GaAsFET wanted for 12 GHz. Write with price and description or data.

K. Boufal
244 Fitzwater Street
Philadelphia PA 19147

I need to borrow Sam's Photofacts numbers SD-13 and SD-15, so that I might photocopy the sections on the Bearcat BC-210 and the BC-250.

Scott Welch
3015 E. Bayshore Blvd. #113
Redwood City CA 94063

I need help writing a program to interface a TI-99/4A computer to a Kantronics UTU.

Bill Trojanowski N2EZG
RD #2
Alpine NY 14805
(607)-594-3544

Teachers/students—I want to get in touch with those interested in forming a net to use communications in the classroom as part of teaching/learning.

Karen KB6DDQ
PO Box 927
Camarillo CA 93011

HELP! I've inherited a Tennelec Memoryscan MS-2 without instructions. I'm looking for a service manual and code book. I'll pay copying and postage.

Gerald Ruettiger
780 So. Woodland
Orange CA 92669

I am looking for a manual for the TT299B/UG MITE Teletype® unit. Will be glad to pay any reasonable price.

Gordon Willard WA0VNK
12764 Allenhurst Drive
Bridgeton MO 63044

I own two Comtron base power amplifiers, 500-Watt model 974-A, 146-174 MHz, and am in desperate need of an operator's/service manual. I'll pay reasonable copying costs and postage.

Mr. Nick Vukelja
Apartado 6-1826
Panama, Rep. of Panama
Tel. 26-7413

I am looking for an instruction manual and schematic for a Dumont 304-A oscilloscope.

Fred Wood WB3JKC
1020 W. Lanvale St. #1
Baltimore MD 21217

I have a TRS-80C, Kantronics software, and an MFJ TU-1224. I would like to use a Model 28 as a printer. Can anyone help?

John Gill
6000 Duda Rd.
House Springs MO 63051

I need schematics, manuals, and any tips I can get for a Browning model ON-5A oscilloscope. I will gladly pay any costs for mailing and copying. Part of the trace is scrunched up on the right-hand side of the CRT.

NEVER SAY DIE
editorial by Wayne Green

from page 6

employees brought a mass of them.

Between the people at *Byte*, WGI, and WGE in Peterborough, I'll bet there are over 500 Wayne Green people in this town of 5,000. It seems as if I get waved at and greeted by almost every other car as I putt around on my new Yamaha.

By passing along the things I have learned through the years, I've helped at least a couple thousand people learn about publishing, electronics, and computers—and that doesn't count the readers I've influenced. I visited one of the computer publishers a few days ago only to find a solid fan who got hooked while reading *73*. He claimed that my editorials pushed him to get into business—drove him to it. He's worth millions today.

We're moving along to start a magazine publishing institute as soon as we can get a building large enough to handle the project. This will be even better than the system I've used in the past, for every student will not only work at every job on a magazine (from proofreading to collecting for advertising), but will be paid for the work. They'll be working on real live publications, too, not just school stuff. No more of this Catch-22 nonsense of having to have practical experience before you can get a job that will let you get practical experience. Graduates will have a resumé citing plenty of good practical professional experience.

I'm hoping to start a yearly alumni meeting at Comdex. So, if you know of anyone who has worked for me during the last 33 years, have them get in touch. I'm having some special coffee mugs made with the logos of all our magazines as souvenirs. Who knows, I may spring for tee-shirts next year! There are lapses in my usual Yankee thrift approach to life.

The dinner will be November 15th in Las Vegas and I want every Wayne Green alumni who can make it to be there. As far as I know, with the exception of two people who betrayed me, one of whom is dead and the other who has completely disappeared from the publishing and computer scene, every alumni is still a darned good friend.

And, with the Green Publishing Institute opening soon, think how many we'll be seeing next year! The whole computer industry is desperately in need of people with publishing experience. This could help enormously to improve the output of spec sheets and instruction books, give the industry much better advertising and catalogs, and so on.

So, alumni, let's get together at Comdex and celebrate! Drop me a note so I can give you details. I'm looking forward to seeing you again, even if you're working for (sob) *Byte* or Ziff-Davis.

NEWSLETTER OF THE MONTH

MAARC
MID-ATLANTIC AMATEUR RADIO CLUB

REMARCS

"All the news that fits, we print" seems an appropriate motto for *REMARCS*, chronicle of the Mid-Atlantic Amateur Radio Club. Editor Kay Craigie KC3LM realizes that no one wants to read endless minutes and committee reports month after month. After all, those who are interested in that brand of tedium can hear it all at the club meeting. Instead, Kay draws upon outside sources such as *Westlink*, *Worldradio*, and the *W5YI Report* to fill *REMARCS* with truly interesting information. For the purist, there are still plenty of club- and member-related articles, and Kay's subtle humor makes even the dreaded meeting announcement a pleasure to read.

On the mechanical side, "immaculate" sums things up. The printing is of professional quality, the pages are nicely composed, and there are no typographical errors to be found. Can you say the same for your group's publication?

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

$$ HOME-BREW III $$

Turn your hot solder into cold cash! Once again, *73* is searching for the greatest home-brewer in the land. All projects have a chance to appear in *73*, and the best of the best will be showered with fame and fortune.

Top prize is $250. Second place is worth $100, and three runners-up will each earn $50. Of course, this is in addition to the payment every author receives for publishing in *73*.

Contest Rules

1. Entries must be received by November 1, 1984.
2. To enter, write an article describing your best home-brew construction project and submit it to *73*. If you haven't written for *73* before, please send an SASE for a copy of our author's guide.
3. Here's the catch: The total cost of your project must be $73 or less, even if all parts were bought new. Be sure to include a detailed parts list with prices and sources.
4. Our technical staff will evaluate each project on the basis of originality, usefulness, reproduciblity, economy of design, and clarity of presentation. The decision of the judges is final.
5. All projects must be original, that is, not previously published elsewhere. There is no limit to the number of projects you may enter.
6. All rights to articles purchased for publication become the property of *73*.
7. Mail your entries to:

73 Magazine
Editorial Offices
80 Pine Street
Peterborough NH 03458
Attn: Home-Brew III

LETTERS

BE A VE

The American Radio Relay League is preparing to serve as a Volunteer Examiner Coordinator (VEC) in each of the 13 FCC call areas (more than one VEC may serve in a particular area). In anticipation of becoming a VEC very soon, the ARRL is recruiting licensed Advanced- and Extra-class radio amateurs to serve as Volunteer Examiners. Applicants are *not* required to be ARRL members to participate. Applicants must, however, hold a current Advanced- or Extra-class license, have no history of license suspension or revocation, and be at least 18 years of age.

The Volunteer Examiner Program covers testing for Technician-, General-, Advanced-, and Extra-class licenses. Novice exams will continue to be given by Novice Examiners under the new Novice rules (97.27 (a) and (c); 97.28 (b); et al); Novice license testing is entirely separate from the Volunteer Examiner Program.

Under the Volunteer Examiner Rules adopted by the Commission, only Advanced- and Extra-class licensees may administer exam elements above the Novice level (97.28 (a)). Extra-class licensees may administer all written and Morse-code elements; Advanced-class licensees may administer only exam Elements 1A, 2, and 3 (Elements required for the Technician license). And, of course, you must be accredited as a Volunteer Examiner by a VEC before you are authorized to administer any upgrade examinations.

If you qualify and are interested in participating as a Volunteer Examiner with ARRL's VE Program, please request an application by writing to Volunteer Examiner Accreditation, American Radio Relay League, 225 Main Street, Newington CT 06111.

Steve Place
ARRL
Newington CT

EARN IT

I agree with the editorial comment in June, 1984, that ham radio is in trouble. There are so many hams like my friend who upgraded a desire to use our designated frequencies to a "right" to those frequencies. There is no such thing as a right. We have to earn the use of the bands

we occupy. The only way I can see to earn them is through the emergency service route. I can't see how we can do it through our advances in technology like we have done in the past. Some hams claim to be advancing technology through their use of computers attached to peripherals for RTTY, CW, packet, AMTOR, and whatever. In my mind those aren't advances. Any Bash graduate who doesn't own a soldering iron can plug those store-bought boxes together and claim he's a great innovator.

But how in the world do we start from scratch and truly do some real ham-style developing? To me that is a serious question.

What's the difference between my sitting here in my shack running my keyboard on AMTOR or packet? I didn't build these things. I bought them. I feel this keyboard operating is not one step above gibbering on SSB. In fact, I think keyboard is beneath CW, particularly on a hand key or my 1939 McElroy Bug! So where do I go technically on the HF bands? (Moonbounce is something else.)

I grant you that traffic by keyboard and printer is a good emergency mode. But damn, I can't see it even after I bought the junk to do it. AMTOR? It's as dull as keyboard CW. Same for packet. No skill.

I'd like to experiment with digital voice. I know how AT&T's "T Carrier" works and their digital radio works, but I don't know how to build an experimental system or where I can get parts if I knew how to do it. So much for my innovating.

Let's test for CW proficiency. Good idea. Let's periodically examine state-of-the-art knowledge as well. Forget this grandfather business and let's make all ticket-holders prove they deserve their operating "rights" and station license.

By definition, I'm not a curmudgeon, but I'm in the retired bracket that you so labeled. I've had a ticket since 1940 and an Extra class since the days when the RI made me send the 20-wpm test on a hand key. I like to experiment, but I do use the KISS approach.

Enough of this blithering. We have to protect the frequencies that we are permitted to use. We need the energy of the young. But I don't know how to attract them. I loaned receivers to two teenagers and about three months later they gave them back and told me that hams are no different from the CBers they talk to. Now what?

I hate to see the ultimate loss of the ham bands, but unless we start earning them, no equipment manufacturers' lobby will save us.

Keep writing and I'll try to stir up some ARES type of action out here.

Ken Uthus KT7E
Nine Mile Falls WA

SUPER

Well, once again I am impressed by *73*. I took a while to type the code program in "Sounds Good to Me," June, 1984. Mike W5VKC/1 and Rick WB5AYD did a great job of putting it together. Congratulations to them for it. They at least took the trouble to translate it for both the VIC-20 and the C-64. That is not done in some magazines.

As per usual, my typing contained a multitude of mistakes. I listed the results to my printer, proofread it (I thought), and sent Mike a copy and asked him to tell me what happened. I was expecting a letter in about a month. I was surprised to receive a personal phone call from Mike (and it was not even collect!). He straightened me out on the mistakes that I had typed in and one that I missed in the translation in his printer. When I corrected my mistakes, the program worked!

Today in the mail I received an MCI Mail from Mike telling me what we discussed over the phone. What service!

Keep up the good work. I have *73*s dated to September, 1968 (73 cents yet). The collection is not complete but it is large. I read with delight your petition to the FCC about the code. I agree with you on your stand on the no-code license and the stiffer theory requirement.

Your *RUN* magazine is on my computer shelf. I have a Commodore 64 and a VIC-20 that I use for RTTY on the HF bands. I am not active on HF now because I need to work over my HF rig. It won't cooperate with me when I send RTTY tones through it. I have the C-64 capable of RTTY through the Santa Fe 147.81/.21 repeater. Not much activity except me right now. Hope I can have someone to talk to soon.

Another of your writers deserves a large pat on the back—Jim Grubbs. I followed his articles in *Commander Magazine*. I corresponded with him via word processor and he was a great help.

Thanks for lending me your ear (eye?), Wayne. Once again keep up the good work. Your people are super.

Alan F. Hill N5BGC
Santa Fe NM

BECKONING BEACON

I have had a beacon operational for over a year. The beacon is on 24 hours a day, seven days a week. Although I have received many QSLs from around the country, a little publicity of the beacon's frequency would be very helpful. I have placed the beacon high in the six-meter band so as not to interfere with local activity and thus it is not easily found. The frequency is 50.440 and the location is Burlington, Connecticut. QSL to K1NFE at PO Drawer M, Plainville CT 06062.

A. DePascale K1NFE
Plainville CT

THANKS, FRANK

I noted in your July, 1984, editorial that you have sold a bunch of your magazines. I sincerely hope this did not include *73*, or at least that you will still retain editorial control over this magazine.

I held a ham ticket from 1948 to 1975, when I let my license lapse, beginning as

✓ See List of Advertisers on page 98

Chief Operator of XAFQ/Trieste, then W5PVE, W2MJF, W8WUN, and W4LJD. I intend to get my code speed back up a bit—I once could copy 35 wpm solid with a stick, but right now 10 wpm poses a bit of difficulty. I'll brush up on theory and take the exam again for a General-class ticket. Then I shall be QRP on CW from 40 through 10. In 1949, I put K4WAR/A4WAR on the air with separate kWs on all bands and a nice antenna farm at Camp (now Fort) Gordon GA. I had some patents issued during the 1950s resulting from electronics design for missile guidance in the 1950s, and from 1955 to mid-1959, I was first a Project Engineer and then a Senior Engineer with Heath Company, Benton Harbor MI.

In fact, I once sold you a short story, "Ed McGurk Makes WAS on Two Meters," which appeared in *CQ* in December, 1955, when you had that magazine—and it was a good magazine then, too. Incidentally, I received $35.00 for the story and Pappy Lynn got $50.00 for the cartoon illustrating it! Maybe I should have been an artist!

Sorry about the reminiscing. What I really started to say was that some months ago I subscribed to *QST*, *CQ*, and *73*. I am letting my subscriptions to *QST* and *CQ* run out, but I'm definitely keeping *73* because it seems to be the best ham magazine among the three at present. I particularly like the construction articles, but then, I like most everything else in the magazine, too. *CQ* isn't totally a loss, but *QST* is a far cry from the great magazine it was in the '40s '50s, and '60s, and definitely not worth the price anymore, to my way of thinking.

I was unaware that you were a Mensan until I noted your name in the *Register* a few years ago. I finally got around to joining the group in 1973 and am still a member.

Anyway, whatever you do, don't let *73* go the way of the other ham rags—I still have about a year to go on my subscription and intend to renew.

J. Frank Brumbaugh
Bradenton FL

CRISIS

I enjoyed your editorial in the June issue of *73* very much. Like your other editorials, it was a breath of fresh air compared to the usual vapid commentaries found in other publications. I completely agree with your comments about Morse code. I have on occasion "read the mail" (a most curious expression) on traffic nets on 2 meters and HF (more on the former) and have been totally amazed at how completely useless and boring it all sounds. In short, your conclusions about the present state of amateur radio are correct, in my opinion.

With the essentials of your argument granted, what can be done to correct the problem? I think it would be useless to go to the ARRL about upgrading the current state of radio technology since they appear to be the bastion of outmoded technology. What other groups in ham radio exist that are interested along these lines, and which could be used to bypass the intellectual ballast residing at the ARRL? (This is clearly, in my opinion, the only course open.)

Finally, are the normal emergency services (i.e., police, fire, civil defense, Red Cross, and National Guard) willing to interconnect with amateur radio? Or do they view amateur radio as completely useless (perhaps with justification)? These are just some of the questions that *need* to be answered. Can you suggest where I might look?

There is one point that you made which is in error. I do not believe that there are more technical graduates in Japan because they have a no-code license. What motivates an individual to go into a particular work? interest in that field *and* the belief that it is worthwhile. If a person is taught that scientific and industrial progress (or progress alone for that matter) is good, then, if he has the interest, he'll choose such a career. But if (as he is taught in the US today) he is taught that scientific and industrial progress is evil, that reason is impotent, etc., then he will not go into those areas, even if he has the interest! After all, why become an engineer when objectivity is impossible and there are more important social concerns (I don't agree with either idea). Thus, this crisis (i.e., lack of young technical people) is just the tip of a larger philosophical crisis, in my opinion! It is a mistake to view it in any other way.

Japan, for the most part (as witness their expansion in reason-oriented areas), does not suffer to the same extent from this philosophical crisis. I believe that the Japanese have a better grasp of the essentials of this issue and are doing better, which is *why* they have a no-code license (i.e., the no-code license is a result and *not* a cause).

Thank you and keep up the good work!

Chris O'Hara N1CRA
Fairfield CT 06432

The bankruptcy of amateur radio is still a well-kept secret. Having worked on NIAC with representatives of the other communications services, I can assure you that word has not yet leaked out as to the disaster we've generated and we will still get full cooperation.—Wayne.

SOFTWARE PIRACY

There is a problem in the amateur-radio fraternity. . .software piracy. Whether by ignorance or simple disregard for the law, many amateurs are stealing copyrighted programs. Most do not consider their theft a crime or a serious problem, but unless this practice is discontinued, amateur radio will suffer.

With the influx of computers into the hobby, a degree of software piracy was inevitable. Unfortunately, the problem has become a blemish on amateur radio. Thousands of dollars have been spent in litigation involving software piracy outside the hobby, and I had hoped amateur radio would police the problem internally and not require legal action. Sadly this is not the case.

I recently confronted two hamfest exhibitors who were selling copies of a Kantronics program. These people were copying and selling our programs to any amateur willing to pay the price. I bought one of the programs for evidence and informed the seller that legal action would be taken. This person was not a ham, but those buying the programs were. We have several other examples of programs copied and sold.

There are a few simple steps we can all take as those interested in seeing the problem solved:

1. Never buy copied software.

2. Report pirates to the software manufacturer.

3. Don't allow illegal sales at your local hamfest.

Kantronics plans to prosecute those who steal our programs, as we have in the past. But without the assistance of the entire amateur community, the manufacturers will not be able to stop pirates from stealing their profits. If manufacturers are not able to sell enough product to make a profit, other new and improved programs will not be written. Don't let the greed of a few deny the hobby of future expansion. Let's throw the bad apples out before they ruin the whole barrel.

Mike Forsyth
Marketing Director
Kantronics, Inc.

SHARING IDEAS

"Perfboard and Soldertail?", which appeared in the July, 1984, issue of 73, has brought some welcome correspondence. The letters below add some important ideas to those in the article. More importantly, they illustrate one of the most important ideas in ham radio: the willingness to share freely experience and ideas that might help other hams. I want to thank both gentlemen for writing and for adding to my own stock of construction ideas. No one knows everything, and perhaps it is even true that none of us knows very much. But together, we know a lot of very useful things about many matters.—L. B. Cebik W4RNL.

I read your article in *73* for July, 1984, "Perfboard and Soldertail?", with interest. I have been a ham for over 40 years and have constructed countless projects. The ideas you described are good, and I picked up a few new thoughts from your text. Many thanks!

I'm writing to pass along a few tips that I have found helpful, in the hopes that you can use them, too. Here they are!

Cutting perfboard and PC material is easy to do without sawing. If you score both sides heavily (I take a couple of passes per side with the board held flat on an old magazine, using a heavy razor knife from the hardware store—the kind of knife that has replaceable blades—I use one made by Millers Falls that stores the blades in the heavy aluminum handle), it will break cleanly along the score. It hardly even needs touch up with a file for neatness, but that is a good finishing touch. I find it much easier than sawing, and I have never had a split or chip.

You are right about pencil marks causing leakage paths with CMOS circuits. Another maddening cause of the same thing is solder flux, which causes a problem when the humidity is high. The only cure I have found is to use a commercial flux remover on the board (Radio Shack's is OK). Isopropyl alcohol does not work well and sometimes makes the problem worse due to its water content.

Forming leads on small parts can be done beautifully with a small pair of "chain-nose" pliers. Available in good hardware stores and hobby shops, the jaws have circular cross section. They are not really as suited for gripping as regular pliers, but they do a swell job of forming nicely rounded bends. I think they were originally designed to make small chain links.

I also find it very helpful to keep one of those tapered red-plastic lead formers handy, to get the exact lead spacing on resistors, etc. I think you can get them from Radio Shack, but I have had mine so long, I am not sure.

I have had problems drilling large holes, say, over about 3/16 inch. I find the board often cracks if the hole is near an edge. I have been using two reamers instead. One is a regular T-handle 1/8-to-1/2-inch size, and the other is a model-maker's reamer (from Brookstone) that goes from almost nothing to about 1/8 inch. Perfboard material is so soft that you can often ream a super quality hole faster than setting up to drill it. It also is a good solution for that hole size for which you don't have a drill.

When mounting a PC or perfboard parallel to the chassis surface, I always have (it seems) minor problems getting all holes to line up. It seems to work better for me to not use 4-point mounting (mounts in the corners), but to use 3-point mounting instead. Generally, when things don't quite line up, only one hole need be moved. Three points determine a plane, and it works well for me.

A really neat way to mount boards, when you are pretty sure the debugging phase is over, is to mount them parallel to the front panel, supported on the front-panel controls. For example, if you have a couple of switches and a pot, it usually is possible to arrange the parts so that selected surfaces are equidistant from the panel surface. You can either epoxy (if you are really sure!) the board to the controls (such as to the back surface of a pot) or (better) solder the lugs of the switches to pads on the PC board through small access holes. It sounds cumbersome, but it often can be done and leads to a really nice looking arrangement. On occasion, I have used this technique by soldering heavier-than-usual leads on the panel controls (#16 or #18 wire) and passing these leads through the perf- or PC board, soldering them to the pads, etc. With several such leads, the whole thing is surprisingly sturdy. The rest of the chassis is yours to do with as you like—it is like free additional space!

When using quite thin wire (such as wire-wrap wire), if the long runs are left quite loose, after the job is done, it can be made to look neater by pulling a loop of the long lead through an unused hole on the perfboard, just to tighten up the lead. Judicious selection of the "stitch" hole can also restore those right-angle bends to otherwise diagonal runs.

A super easy way to make PC boards from articles when you wish to etch the board conductors is to do the job backwards. Instead of etching and then drilling, make a photocopy of the board from the magazine and scotch tape it to the PC board. Using a small drill (I really prefer the hand-held battery-powered jobs; they are easier to control and more convenient than a big drill or a Dremel tool, unless you have a permanent shop setup), drill right through the photocopy and your PC board, until all holes are in place. Then remove the photocopy, deburr as necessary, and scrub the copper surface in the kitchen sink using SOS scouring wool. When the copper is bright, rinse it and leave the tiniest trace of regular dishwashing detergent on the surface. It will cause etch-resist pens to write beautifully. With little effort and practice, you can draw the conductors; you can even make a hybrid arrangement with some prepared wax patterns, IC pads, if you wish. It is also your golden opportunity to add your name, call, date, revision number, or whatever. After the board is etched, a little cleaning is all you need before stuffing. Try it, you'll like it!

As I said, I enjoyed your article and hope you find one or more of my ideas to be helpful, too.

Warren Offutt AF9Q
Geneva IL

I read your article in *73* on perfboard construction practice. Very thorough, but I would like to add my two cents:

I have gravitated away from using phenolic perfboard because it is so *fragile* and doesn't have a high enough insulation resistance for some high-impedance

circuits. The same goes for epoxy paper. They are moisture sensitive.

I prefer to use G10 or FR4 (or similar) epoxy-fiberglass perfboard. One source is Vector P pattern, available from industrial electronics parts houses. It is easily cut by scoring it on both sides with a utility knife held against a straightedge, clamping the part in a vise or between a tabletop edge and a rigid sheet of metal, etc., and then giving it a "karate chop" to get a clean break. The extra expense of the premium perfboard is well worth it in avoiding duplication of effort if the circuit is dropped or doesn't work right.

I have even used G10 perfboard for rf circuits. Vector sells a version with *continuous copper* on both sides. Isolated pad "cookie cutters" are then used to develop a circuit. These tools are available from Vector or A. F. Stahler (if they are still in business). Stahler parts were carried by Trumbull (if he is still in business). I believe I bought a "bubble etcher" from Trumbull a while ago, but I have mislaid it because I have moved several times since. I would like to locate Trumbull again or someone who has taken over the line. I use perfboard for breadboards and prototypes, and PC for finished models if it is worth the effort.

Two useful tools for working epoxy-glass perfboard are a "nibbling tool" (to cut irregularly shaped holes) and a "tapered reamer" (to enlarge round holes drilled with a hand-twist drill chuck). These are available from Sears, Radio Shack, etc.

I agree that it is wise to socket all semiconductors in a breadboard. Also, those threaded metal spacers (Mouser? et al) are very useful to aid in mounting. Masking tape and a ball-point pen can provide labels of important circuit tap points. Wiring going off the perfboard should be stranded/insulated, but solid insulated will work on-board.

Well, that's all I have to relate, now. I am not a ham yet but am an electrical engineer in telecommunications circuit design. I am working towards a Technician's license because I got interested in homebrew microwave and satellite TV links and need a ticket to transmit. MDS downconverters can be used on 2304 MHz.

Keep up the good work. With much of electronic technology going to Japan, it is difficult for a new engineer to gain practical experience. Ham radio is a useful thing to an American technician or engineer wishing to hone his skills.

Raymond Barcklow, Jr.

WORLDWIDE AWARDS DIRECTORY

If you like to go after awards or win contests, this directory is a must! Volume 1 lists over 270 awards from all over the world with names and addresses, costs, and descriptions. $9.95 brings Volume 1 to your doorstep. Volume 2 is in production now and will cost $5.95 for an additional 130 awards. Why not order Volumes 1 and 2 for a combined price of $12.75? The *Worldwide Awards Directory* is for the amateur-radio operator who is interested in showing his proficiency at radio communications to others throughout the world. You will never know how easy it is unless you know how to go about it. You probably already have enough QSLs in your files for some of the awards. $9.95 includes all postage and handling. COD extra. Quantity discounts available.

Also, if you know some awards that you would like listed, please let Larry know and they will appear in the next volume. Write to: Larry Kebel KBØZP, 736 39th Street, West Des Moines IA 50265.

INLAND STEEL ARA

The Inland Steel Amateur Radio Association will operate special-event station K9DWL to commemorate The Little Red School House and Hammond, Indiana's centennial year, from 1400Z to 0000Z on Saturday, October 6, 1984. Frequencies: phone—General-class portions of 10, 15, 40, and 80 meters; CW—Novice-class portions of 10, 15, 40, and 80 meters; 2-meter *FM—146.42 simplex.* Send legal-size SASE for certificate to Lucy Schendera N9DTG, 812 E. 40th Place, Griffith IN 46319.

ST. PETERS ARC

The St. Peters Amateur Radio Club will operate a special-event station from 1700 UTC, Saturday, October 6, to 1700 UTC, October 7, at the Daniel Boone Home, Femme Osage Valley, St. Charles County, Missouri. The event is to commemorate the place where Daniel Boone; frontiersman, judge, trapper, surveyor, builder, and family man, spent the last twenty years of his life. The weekend celebration features a black powder marksman contest for local participants. One complete 2-way contact is needed to obtain a presentation-quality certificate on aged parchment featuring a picture of the Boone Estate and an information brochure of Boone facts. SPARC will operate KBØJ on plus or minus 3.915, 7.240, 14.280, 21.420 depending on conditions and band activities. A coonskin cap will also be awarded to the first operator making contact on all four bands. One dollar or 3 IRCs with calls and time of contact should be sent to Tim Haake WAØTSY, 128 Lake Point Drive, St. Peters MO 63376.

CENTER OF THE US

The Central Kansas ARC of Salina KS will operate WØKQU from the marker of the geographical center of the US in Lebanon KS. Operation will be from 1700Z October 6 till 1900Z October 7, 10 kHz up from the lower end of the General-class 10-80-meter bands. Certificate via KBØBH, 2358 Aurora Ave., Salina KS 67401.

COLUMBUS DAY

The Columbus Amateur Radio Association will be holding its second annual Columbus Day Special Event to provide a triple salute to Christopher Columbus, the City of Columbus, and amateur radio worldwide, on October 6-7, 1984. CARA's club station, W8TO, *located* at the Center of Science and Industry, will try to contact as many stations as possible around the world.

Eligibility

Open to all amateur-radio operators worldwide, to be divided into two groups: Columbus OH (and suburbs) amateurs; all other amateurs.

Bands

Saturday, October 6, 1984—1400Z to 2400Z—15 meters phone at 21.375 MHz ± 10 kHz.

Sunday, October 7, 1984—1400Z to 2400Z—40 meters phone at 7.240 MHz ± 10 kHz.

Exchange

Name, QTH, and RST.

Scoring

One point for each contact (excluding W8TO), six points for a W8TO contact. A final score of 10 must be submitted to be eligible for a certificate. Scores must be submitted within 120 days to be valid. Certificates will be issued to all qualifying amateurs who include an SASE (SAE and 3 IRCs for DX). SWLs may receive the certificate on a station-heard basis.

A mini contest will be in operation during the event *period; the highest score* from a Columbus amateur will receive a plaque.

All requests for certificates and correspondence should be sent to Amateur Radio Station W8TO, Attn. Special-Event Coordinator, 280 East Broad St., Columbus OH 42315.

CENTER OF US POPULATION

The Jefferson County Amateur Radio Club will be operating special-event station KAØIAR from De Soto MO, the center of US population, on October 13, 1984, from 1500Z to 2400Z.

Operation will be in the lower ends of the 40-, 20-, and 15-meter General bands. There will be some CW in the Novice portion of the same bands.

For a certificate, send an SASE and QSL to KAØIAR, 3009 High Ridge Boulevard, High Ridge MO 63049.

HAT ROCK

The Hermiston Amateur Radio Club will operate KC7LK from Hat Rock State Park from 1800 GMT, October 13th, to 0100 GMT, October 14th, and between 1800 and 2200 GMT on October 14th. The station is commemorating the 179th anniversary of Lewis and Clark's visit to Hat Rock and will be operating in conjunction with the Oregon QSO party.

Operation will be on the General phone and Novice CW bands. There will also be some 2-meter and 440-MHz operation. For a certificate, send on SASE and your contact number to the Hermiston Amateur Radio Club, PO Box 962, Hermiston OR 97838.

QUEEN CITY

The Clarksville Amateur Transmitting Society will be operating a special-event station celebrating the 200th anniversary of Clarksville TN, the Queen City on the Cumberland River. The dates and times are as follows: October 13, 1984, from 1400Z to 2400Z and October 14, 1984, from 1800Z to 2200Z. The call of this station will be N4GMT. Modes of operation will be SSB, CW, and RTTY. Frequencies of operation will be around 21.375 MHz, 14.280 MHz, and 7.240 MHz. A commemorative QSL certificate will be sent for every SASE received. QSL via KB4EFW, Rt. 1 Box 162A, Indian Mound TN 37079.

SUNBELT AGRICULTURAL EXPO

The Colquitt County Ham Radio Society will be operating club station WD4KOW from the site of the seventh annual Sunbelt Agricultural Exposition on October 16, 17, and 18, 1984. The hours of operation will be 0900 to 1700 EDST each day.

This annual Sunbelt Expo is held each year at Spence Field Airbase, located near Moultrie, Georgia, and is the largest agricultural show in the South. This event draws over *200,000 visitors from all* over the United States and foreign countries.

Operations will be in the General portion of the HF bands. The members will also be listening for visiting hams on the local repeater 146.19/.79. Visiting hams are invited to visit the amateur booth at the Expo and operate the amateur station.

A special OSL card is available for those making contact during this event and submitting an SASE.

J. GORDON COOGLER POETRY FESTIVAL

On Saturday, November 3, 1984, K4MJN will operate a special-event station in Blythewood SC to commemorate the birthplace of J. Gordon Coogler (1865-1901).

J. Gordon Coogler has been acclaimed by literary critics as the WORST practicing poet in US literary history! His verses are now known as Cooglerisms, as is any other work since that falls into that same critical disdain. Many literary societies of today award the Coogler Award for the worst published works of the year. But here in Blythewood (Population 93) we're very proud of our native son and celebrate his accomplishments with a festival and poetry contest.

K4MJN will operate on or around 14.290 MHz from 1400Z to 1800Z and on or around 21.390 MHz from 1800Z to 2200Z. Join us!

All stations working K4MJN during this second annual festival will receive a handsome certificate with a photo of The Bard of Blythewood and some of his poetry. Send a large business-size SASE with your QSL and contact number to J. David Suggs K4MJN, Rt. 3, Box 154, Blythewood SC 29016.

BOMB SQUAD

The BOMB Squad (Best of Mt. Baldy) will operate W6HCP (Hollywood Christmas Parade) from 1600Z on November 25 to 0400Z on November 26, 1984. Operation from the parade communications center of the 1984 Hollywood Christmas Parade will be on 7.284, 14.284, and 21.284 MHz, SSB. SASE to W6GVR for special commemorative QSL.

WORKED ALL ZONES

The WAZ Award is issued to any licensed amateur station presenting proof of contact with the forty zones of the world. This proof shall consist of proper QSL cards, which may be checked by any of the authorized *CQ* checkpoints or sent directly to Mr. Leo Haijsman W4KA, WAZ Award Manager, 1044 Southeast 43rd St., Cape Coral FL 33904. Many of the major DX clubs in the US and Canada and most national amateur-radio societies abroad are authorized *CQ* checkpoints. If in doubt, consult the WAZ Award Manager. Any legal type of emission may be used, providing communication was established after November 15, 1945.

The official *CQ* WAZ zone map and zone list will be used in determining the zone in which a station is located.

Confirmation must be accompanied by a list of claimed zones using *CQ* form 1479, showing the call letters of the station contacted within each zone. The list should also clearly show the applicant's name, call letters, and the complete mailing address. The applicant should indicate the type of award for which he is applying, such as all-SSB, all-CW, or mixed. In remote locations and in foreign countries, a handwritten list may be submitted and will be accepted for processing, provided the above information is shown.

All contacts must be made with licensed, land-based, amateur stations operating in authorized amateur bands.

All contacts submitted by the applicant must be made from within the same country. It is recommended that each QSL clearly show the station's zone number. When the applicant submits cards for multiple callsigns, evidence should be provided to show that he or she also held those call letters.

Any altered or forged confirmations will result in permanent disqualification of the applicant.

Include with the application the processing fee (*CQ* subscribers—$4.00; nonsubscribers—$10.00) and a self-addressed envelope with sufficient postage stamps or IRCs to return the QSL cards by the class of mail desired and indicated. *CQ* subscribers should include a recent mailing label (or copy) with application. IRCs equal in redemption value to the processing fee are acceptable. Checks should be made out to Mr. Leo Haijsman, WAZ Award Manager.

In addition to the conventional certificate for which any and all bands and modes may be used, specially endorsed and numbered certificates are available for phone and single-sideband operation. The phone certificate requires that all contacts be two-way phone; the SSB certificate requires that all contacts be two-way SSB.

If, at the time of the original application, a note is made pertaining to the possibility of a subsequent application for an endorsement or special certificate, only the missing confirmations required for that endorsement need be submitted with the later application (provided a copy of the original authorization signed by the WAZ manager is enclosed).

Decisions of the *CQ* DX Awards Advisory Committee on any matter pertaining to the administration of this award will be final.

All applications should be sent to the WAZ Award Manager after the QSL cards have been checked by an authorized *CQ* checkpoint.

Zone maps, printed rules, and application forms are available from the WAZ Award Manager. Send a self-addressed envelope (4" × 9-1/2") with 28 cents postage, or a self-addressed envelope and 2 IRCs. For rulings on borderline areas, consult the WAZ Award Manager.

Single-Band WAZ

Since January 1, 1973, WAZ Awards have been issued to licensed amateur stations presenting proof of contact with the 40 zones of the world on one of the five high-frequency bands, 80-10 meters. Contacts for a single-band WAZ award must have been made after 0000 hours GMT, January 1, 1973. Proof of contact shall consist of proper QSL cards checked by the DX Editor, the WAZ Manager, or an authorized *CQ* checkpoint. Single-band certificates will be awarded for both two-way phone (including SSB) and two-way CW. The single-band WAZ program is governed by the same rules and uses the same zone boundaries as the regular WAZ Award.

5-Band WAZ

On January 1, 1979, the *CQ* DX Department, in cooperation with the *CQ* DX Advisory Committee, announced the 5-band WAZ.

Applicants who succeed in presenting proof of contact with the 40 zones of the world on the five high-frequency bands—80, 40, 20, 15, and 10 meters (for a total of 200)—will receive a special certificate in recognition of this achievement.

These rules were in effect as of July 1, 1979, and supercede all other rules. Five-band WAZ will be offered for any combination of CW, SSB, phone, or RTTY contacts, mixed mode only. Separate awards will not be offered for the different modes. Contacts must have been made after 0000 hours GMT, January 1, 1979. Proof of contact shall consist only of proper QSL cards checked by the WAZ Award Manager. The first plateau will be a total of 150 zones on a combination of the five bands. Applicants should use a separate sheet for each frequency band, using *CQ* form 1479.

A regular WAZ or single-band WAZ will not be a prerequisite for a 5-band WAZ certificate. All applications should show the applicant's WAZ number.

After the 150-zone certificate is earned, the final objective is 200 zones for a complete 5-band WAZ. *CQ* is donating plaques for the first 5 winners, after which the applicant will have a choice of paying a fee for his plaque and/or applying for an endorsement commemorating this achievement.

The applications should be sent to the WAZ Award Manager. The 5-band Award is governed by the same basic rules as the regular WAZ and uses the same zone boundaries.

PETERBOROUGH ARC

The Peterborough (Ontario) Amateur Radio Club is offering a distinctive bicentennial certificate to amateurs contacting Peterborough amateur stations during 1984. Ontario stations must contact five Peterborough amateurs, North American stations must contact two, and DX stations must contact one. Use any band, any mode.

Send $1 and a list of contacts as well as date and time of contact (no QSLs required) to: Peterborough Amateur Radio Club, PO Box 1205, Peterborough, Ontario K9J 7H4.

ISLAND DX AWARD

The IDX Award, sponsored by the Whidbey Island DX Club, is one of the most sought after awards in the DX community. This award is available to licensed amateurs and shortwave listeners worldwide.

The IDX Award is issued for SSB, CW, RTTY, SSTV, and mixed mode, as well as for mixed- and single-band accomplishments. Applicants must work fifty (50) IDX islands for the basic award. Endorsements are given in increments of 50 islands, up to and including the maximum number of islands possible.

Only DXCC countries which are bona fide "islands" are qualifying contacts. A special IDX listing appears within this column. To be valid, all contacts must have been made after October 1, 1977.

To apply, prepare a list of qualifying contacts in prefix order. Please number your contacts 1 through 50, etc. Include the call of the station worked, IDX island name, band, mode, date, and GMT.

Do not send QSL cards! Have your list verified by two amateurs or local radio-club officials. Confirmation of each contact must be in the applicant's possession at the time it is being verified. Send list of contacts along with $4 in US funds only and a business-size SASE to the following address (foreign stations may substitute 20 IRCs for the fee): Whidbey Island DX Club, Attn: IDX Award, 2665 North Busby Road, Oak Harbor WA 98277.

Rules governing this award program are reviewed annually in the month of September. Please enclose an SASE with any enquiries regarding this award program.

The IDX Awards Program uses DXCC countries which are bona fide "islands" as recognized by the National Geographic Society. The first criterion is that each must have been a DXCC country on or after October 1, 1977, as stated on the DXCC List of the ARRL. Any "qualifying" DXCC country omitted from this list by error or which has been recognized for DXCC after the release of this listing will be added the next time it goes to press. In the meantime, applicants may count the new countries in their tally.

HAROAA AWARDS

These awards are of high quality and will make a very nice addition to any radio room. The awards are available to all licensed amateurs and amateur stations. Please do not send QSL cards. A list showing full details of the contacts (log information) should be certified by one other amateur or radio-club officer. Photocopies of your QSL cards or original log will also be permitted. At your request,

special endorsements will be added such as: CW, SSB, all YL, QRP, RTTY, SSTV, one band, etc. If you so desire, you may request separate awards for each special endorsement. Contacts may be made over any period of years. Contacts made through repeaters cannot be used. Satellites are permitted. Please pass this award information along to another amateur or post it at your local club. All correspondence or applications should be sent to: HAROAA, PO Box 341, Hinckley OH 44233, Attn: Awards Manager Gary Zimmerman WB8RTR.

Application for each award must be accompanied by three US dollars to cover handling and award costs. Payment may be made by cash, personal check, money order, ten IRCs, or first-class-rate US postage stamps. DX applicants may send a money order made out in US funds, ten IRCs, or any of the above.

If at any time your award is lost, misplaced, or damaged in any way, send the date, award number, and pertinent information and we will replace it free of charge. All awards include the special HAROAA gold seal.

Great Lakes Award

This requires one contact with each state bordering the Great Lakes: New York, Pennsylvania, Ohio, Michigan, Indiana, Illinois, Wisconsin, and Minnesota.

Super Certificate Hunter Award

This HAROAA award is designed for the serious certificate hunter. To earn this award, you must have a minimum of ten amateur-radio operating awards. Simply list the awards that have been issued to you. Special endorsements are 10, 25, 50, 75, and 100 plus.

HAROAA DX Award

This is obtained by working DX stations. It is the number of stations worked that is important. Each DX station counts as one, even if several are from the same country or area. Special endorsements for this award are 10, 25, 50, 75, 100, 200, and 500 DX contacts.

HAROAA Insomnia Award

This award is earned by communicating with one other amateur-radio station for a minimum of one hour between the hours of 1:00 and 5:00 am. A super conversation piece for your shack.

HAROAA Super Operator Award

This certificate is rendered for those providing a service on behalf of amateur radio such as weather observation, public service, emergency work, helping a new ham, providing communications for a community function, etc. The requirements are for the applicant to briefly describe the event or service. The officials of HAROAA will determine whether it deserves this special recognition.

HAROAA Official Traffic Handler Award

This award is a self-issued achievement, allowing you to display the fact that you are indeed an official handler of radio traffic.

WORKED TRUMBULL COUNTY AWARDS

The Warren (Ohio) Amateur Radio Association, Inc., announces its Worked Trumbull County (WTC), Worked Trumbull County Mobile (WTC-M), and Worked Trumbull County YL (WTC-YL) awards. These programs are designed to promote increased amateur-radio activity among and with Trumbull County amateur-radio operators. The awards also reward operating achievements.

Application: Send applications and all correspondence to: Don Lovett K8BXT, Awards Chairman, WARA, PO Box 809, Warren OH. One dollar must accompany applications from W, K, and VE amateurs; all others should send three IRCs with application. Only Trumbull County applicants must submit actual QSL cards. All others should have certification letters from two other radio amateurs which verify that they have seen and checked the applicant's QSLs. Each application must also be accompanied by a list of the calls worked, with full log data for each contact.

Requirements

WTC—For each certificate or endorsement, Trumbull County applicants must have 20 contacts with other Trumbull County amateurs. Other W, K, and VE stations must contact 10 Trumbull County amateurs, while DX applicants must have five contacts.

WTC-M—For each certificate or endorsement, Trumbull County applicants must have 20 contacts with other Trumbull County amateurs operating mobile in Trumbull County. Other W, K, and VE stations must contact 10 Trumbull County amateurs operating mobile in Trumbull County, while DX applicants must have five contacts.

WTC-YL—For each certificate or endorsement, W, K, and VE stations must contact 10 Trumbull County YL or XYL amateurs, while DX applicants must have three contacts.

Award: A certificate will be issued on each approved application but in order to appear on the certificate, special endorsements must be filed with the initial filing, each containing at least 25 percent new contacts. Initial endorsements are free of charge, but endorsements made on later dates will take the form of WTC certificates. Applications for these must contain proper filing fees. Endorsements may be all one mode, all one band, all mobile-to-mobile, or all members of the Warren Amateur Radio Association, Inc.

Net contacts, contacts made through repeaters, and contacts made before January 1, 1959, cannot be counted.

A FAR NET AWARD

The Armored Force Amateur Radio Net is a nonprofit and informal group of amateur-radio operators who are veterans or active-duty service personnel who have been assigned or attached to an armored unit of the United States Armed Forces or their allies at some time in their military careers.

The A FAR NET offers its A FAR NET Award certificate to amateur-radio operators of any nation. The 8½" × 11" certificate is printed in four colors on white on heavy stock and is intended for framing. Endorsements are available for making additional contacts and for making contacts in one mode or on one band. Application may be made for any award level, mode, or band operation at any time.

To qualify for the basic award, nonmember stations must establish two-way contact with a minimum of fifteen different A FAR NET member stations. To qualify for endorsements, non-member stations must make contact with ten or thirty-five additional members on any band or in any mode. Confirmation of the required contacts must be through a copy of the non-member's log that has been certified by two other amateur-radio operators.

Applicants for the basic award certificate must submit a minimum of fifty cents along with their application to cover postage, envelopes, etc. Endorsements not mailed along with the basic certificate will require only a normal 4½" × 6" SASE. Applications for the basic award or endorsements should be sent to: Alfred G. Beutler K2DWI, A FAR NET Certificate Manager, 36 Manchester Road, East Aurora, New York 14052. Please allow from two to four weeks for mailing of the certificates or endorsements.

HONG KONG AWARDS

HARTS meets every Tuesday at 1700 local, excluding public holidays, at the China Fleet Club, Arsenal Street, Wanchai, Hong Kong Island.

Nine Dragons Award

This award is given for one contact with a country in each of the following 9 zones: 18, 19, and 24 to 30. Contact for zone 24 must be a VS6. Stations within the 9 zones require 2 contacts in each zone, with 2 VS6 contacts. Only contacts after January 1, 1979, are valid. Fees are US $3, Australia $3, 1 pound 50 pence England postal order, or 24 IRCs.

Firecracker Award

This award is given for six contacts with different VS6 stations. Stations in zones 18, 19, and 24 to 28 require 10 contacts with different VS6 stations. Only contacts after January 1, 1964, are valid. Fees are US $2, Australia $2, 1 pound England postal order, or 10 IRCs.

Usual Conditions

Certified log extracts only—no QSL cards are required. Payment to be made in cash—no bank drafts. Postal orders to be left blank. Claims to: Awards Manager, HARTS, GPO Box 541, Hong Kong.

FEDERAL COMMUNICATIONS COMMISSION

47 CFR Parts 1 and 97

[PR Docket No. 83-27; RM-4229; FCC 84-324]

Use of Volunteers To Prepare and Administer Operator Examinations in the Amateur Radio Service

AGENCY: Federal Communications Commission.

ACTION: Final rule.

SUMMARY: This document amends the FCC rules regarding the preparation and administration of amateur radio operator examinations above the Novice Class to permit Volunteer-Examiner Coordinators (VEC's) and volunteer examiners to design the examinations instead of the FCC. This amendment will relieve the FCC of the administrative burden of designing the examinations and permit VEC's and examiners more latitude in preparing and administering examinations. This document also amends certain other FCC rules regarding the Amateur Radio Service volunteer examiner program to clarify them.

EFFECTIVE DATE: August 31, 1984.

FOR FURTHER INFORMATION CONTACT: John J. Borkowski, Private Radio Bureau, Washington, D.C. 20554, (202) 632-4964.

Appendix

Parts 1 and 97 of the Commission's Rules (47 CFR Parts 1 and 97) are amended as follows:

PART 1—[AMENDED]

1. Paragraph (e) of § 1.925 is revised to read:

§ 1.925 Application for special temporary authorization, temporary permit or temporary operating authority.

* * * * *

(e) Unless the FCC otherwise prescribes, an applicant already licensed in the Amateur Radio Service, upon successfully completing the amateur radio operator examination(s) required for a higher class, may operate his/her amateur radio station consistent with the rights and privileges of that higher class for a period of one year from the date of the most recently completed examination(s) for that operator class in accord with the provisions of § 97.35.

PART 97—[AMENDED]

2. The Table of Contents for Part 97 is amended as follows:

a. The heading of § 97.517 is revised to read "Examinations."

b. The heading of § 97.523 is removed.

3. Paragraphs (a), (b), and (d) of § 97.27 are revised to read:

§ 97.27 Examination preparation.

(a) Element 1(A) shall be prepared by the examiner. The preparer must hold an Amateur Extra, Advanced or General Class operator license. The test shall be such as to prove the applicant's ability to transmit correctly by hand (key, straight key, or, if supplied by the applicant, any other type of hand operated key such as a semi-automatic or electronic key, but not a keyboard keyer) and to receive correctly by ear texts in the international Morse code at a rate of not less than five (5) words per minute during a five-minute test period. Special procedures may be employed in cases of physical disability. (See § 97.26(g).) The applicant is responsible for knowing and may be tested upon the twenty-six letters of the alphabet, the numerals 0–9, the period, the comma, the question mark, $\overline{\text{AR}}$, $\overline{\text{SK}}$, $\overline{\text{BT}}$, and $\overline{\text{DN}}$. (See § 97.29(c).)

(b) Elements 1(B) and 1(c) shall be prepared by the examiners or be obtained by the examiners from the VEC. The preparer must hold an Amateur Extra Class license. The test shall be such as to prove the applicant's ability to transmit correctly by hand (key, straight key, or, if supplied by the applicant, any other type of hand operated key such as a semi-automatic or electronic key, but not a keyboard keyer) and to receive correctly by ear texts in the international Morse code at not less than the prescribed speed during a five-minute test period. Special procedures may be employed in cases of physical disability. (See § 97.26(g).) The applicant is responsible for knowing and

may be tested upon the twenty-six letters of the alphabet, the numerals 0–9, the period, the comma, the question mark, AR, SK, BT and DN. (See § 97.29(c).)

• • • • •

(d) Elements 3, 4(A) and 4(B) will be designed by the VEC. The VEC will select questions for each test from the appropriate list of questions approved by the Commission (either PR Bulletin 1035 B, C or D, latest date of issue). The VEC must select the appropriate number of questions from each category of the syllabus (PR Bulletin 1035) as specified in PR Bulletin 1035 B, C or D. These questions must be taken verbatim from the appropriate PR Bulletin in the form in which they have been approved by the Commission. Beginning January 1, 1987, volunteer examiners may also design Elements 3, 4(A) and 4(B) in accord with the provisions of this paragraph. Each VEC and each volunteer examiner is required to hold current examination designs in confidence.

• • • • •

4. Paragraphs (a) and (e) of § 97.28 are revised to read:

§ 97.28 Examination administration.

(a) Unless otherwise prescribed by the Commission, each examination for an amateur radio operator license (except the Novice Class operator license) shall be administered by three accredited (see § 97.515) volunteer examiners. An examiner administering telegraphy examination element 1(A) or written examination element 2 (in conjunction with an examination other than a Novice Class examination) or written examination element 3 must hold an Amateur Extra Class or Advanced Class radio operator license. An examiner administering telegraphy examination element 1(B) or 1(C) or written examination element 4(A) or 4(B) must hold an Amateur Extra Class radio operator license.

• • • • •

(e) When the candidate scores a passing grade on an examination element, the examiners (except for examinations for the Novice Class operator license) must issue a certificate of successful completion of the examination. This certificate may be used for a period of one year for examination credit for telegraphy elements 1(A), 1(B) or 1(C). (See § 97.25(b).)

• • • • •

5. Paragraph (b) of § 97.31 is revised to read:

§ 97.31 Volunteer examiner requirements.

• • • • •

(b) Any person who owns a significant interest in, or is an employee of, any company or other entity which is engaged in the manufacture or distribution of equipment used in connection with amateur radio transmissions, or in the preparation or distribution of any publication used in preparation for obtaining amateur station operator licenses, is ineligible to be a volunteer examiner for purposes of administering an amateur radio operator examination. However, a person who does not normally communicate with that part of an entity engaged in the manufacture or distribution of such equipment, or in the preparation or distribution of any publication used in preparation for obtaining amateur operator licenses, is eligible to be a volunteer examiner.

• • • • •

6. Section 97.35 is revised to read:

§ 97.35 Temporary operating authority.

Unless the FCC otherwise prescribes an applicant already licensed in the Amateur Radio Service, upon successfully completing the amateur radio examination(s) required for a higher class, may operate an amateur radio station consistent with the rights and provileges of that higher class for a period of one year from the date of the most recently completed examination for that operator class provided that the applicant retains the certificate(s) for successful completion of the examination(s) (see § 97.28(e)) at the station location, provided that the applicant uses the identifier code of the new class of license for which the applicant has qualified (KT for Technician Class, AG for General Class, AA for Advanced Class and AE for Amateur Extra Class) as a suffix to the present call sign (see § 97.84), and provided that the FCC has not yet acted upon the application for a higher class of license.

7. Paragraph (f) of § 97.84 is revised to read:

§ 97.84 Station identification.

• • • • •

(f) When operating under the temporary operating authority permitted by § 97.35 with privileges which exceed the privileges for the class of operator license currently held by the licensee, a licensee must identify in the following manner:

(1) On radiotelephony, by the transmission of the station call sign, followed by the word "temporary", followed by the identifier code for the new class of license for which the licensee has qualified (see § 97.35).

(2) On radiotelegraphy, by the transmission of the station call sign, followed by the fraction bar DN, followed by the identifier code for the new class of license for which the licensee has qualified (see § 97.35).

• • • • •

8. Paragraph (a) of § 97.503 is revised to read:

§ 97.503 Definitions.

• • • • •

(a) *Volunteer-examiner coordinator* (VEC). An organization which has entered into an agreement with the Federal Communications Commission to coordinate the efforts of volunteer examiners in preparing and administering examinations for amateur radio operator license.

• • • • •

9. Section 97.505 is revised to read:

§ 97.505 Applicability of rules.

These rules apply to each organization that serves as a volunteer-examiner coordinator.

10. Section 97.509 is revised to read:

§ 97.509 Conflicts of interest.

An organization engaged in the manufacture or distribution of equipment used in connection with amateur radio transmissions, or in the preparation or distribution of any publication used in preparation for obtaining amateur radio station operator licenses may be a VEC only upon a persuasive showing to the Commission that preventative measures have been taken to preclude any possible conflict of interest.

11. Section 97.511 is revised to read:

§ 97.511 Agreement required.

No organization may serve as a VEC until that organization has entered into a written agreement with the Federal Communications Commission to do so. The VEC must abide by the terms of the agreement.

12. Section 97.517 is revised to read:

§ 97.517 **Examinations.**

A VEC will design (see § 97.27(d)), assemble, print and distribute written examination Elements 3, 4(A) and 4(B). A VEC may design, assemble, print and distribute examination Elements 1(B) and 1(C). A VEC is required to hold examination designs in confidence.

§ 97.523 **[Removed]**

13. Section 97.523 is removed and reserved.

47 CFR Part 97

[PR Docket No. 82-83; RM Nos. 3705, 3729, 3734, 3778, 3831, 3833, 3880; FCC 84-345]

Radiotelephony Expansion High Frequency Amateur Bands; RM-4228 Petition for Telephony Operations on Frequencies Between 7075-7100 kHz in Hawaii and in Areas Near Region 3

AGENCY: Federal Communications Commission.

ACTION: Final rule.

SUMMARY: This document amends the rules by expanding telephony privileges on frequencies 3750-4000 kHz, 21200-21450 kHz, 28300-29700 kHz, and 7075-7100 kHz (Hawaii and in areas near Region 3). These amendments are necessary so that amateur radio operators will have additional radiotelephone frequencies on which to operate. The result of this action is to relieve the overcrowding on the presently-allocated frequencies for radiotelephony in the Amateur Radio Service.

EFFECTIVE DATE: 0001, Universal Coordinated Time (UTC), September 1, 1984.

ADDRESS: Federal Communications Commission, Washington, D.C. 20554.

FOR INFORMATION CONTACT: Maurice J. DePont, Private Radio Bureau, Washington, D.C. 20554, (202) 632-4964.

Appendix

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended, as follows:

1. Section 97.7(a) is revised as follows:

§ 97.7 **Privileges of operator licenses.**

(a) Amateur Extra and Advanced Class. All authorized amateur privileges including exclusive frequency operating authority in accordance with the following table:

Frequencies	Class of license authorized
3500-3525 kHz	Amateur extra only.
3750-3775 kHz	Do.
7000-7025 kHz	Do.
14,000-14,025 kHz	Do.
14,150-14,175 kHz	Do.
21,000-21,025 kHz	Do.
21,200-21,225 kHz	Do.
3775-3850 kHz	Amateur extra and advanced.
7150-7225 kHz	Do.
14,175-14,225 kHz	Do.
21,225-21,300 kHz	Do.

2. In § 97.61(a), that portion of the table under the heading "kHz" is revised to read as follows. The entries in the table under the headings "MHz" and "GHz" remain the same.

§ 97.61 **Authorized frequencies and emissions.**

(a) * * *

Frequency band	Emissions	Limitations (see paragraph (b))
Kilohertz		
1800 to 2000	A1, A3	
3500 to 4000	A1	
3500 to 3750	F1	
3750 to 4000	A3, A4, A5, F3, F4, F5	4
4383.8	A3A, A3J	13
7000 to 7300	A1	3, 4
7000 to 7150	F1	3, 4
7075 to 7100	A3, F3	11
7150 to 7300	A3, A4, A5, F3, F4, F5	3, 4
14000 to 14350	A1	
14000 to 14150	F1	
14150 to 14350	A3, A4, A5, F3, F4, F5	
21000 to 21450	A1	
21000 to 21200	F1	
21200 to 21450	A3, A4, A5, F3, F4, F5	
28000 to 29700	A1	
28000 to 28300	F1	
28300 to 29700	A3, A4, A5, F3, F4, F5	

3. Secton 97.81(b) (11) is revised to read as follows:

§ 97.61 **Authorized frequencies and emissions.**

* * * * *

(b) * * *

(11) The use of A3 and F3 in this band is limited to amateur radio stations located outside Region 2 and amateur radio stations located within Region 2 which are west of 130 degrees West longitude.

47 CFR Part 97

[PR Docket No. 84-288; FCC 84-322]

Reimbursement of Out-of-Pocket Costs for Volunteer Administered Amateur Radio Examinations

AGENCY: Federal Communications Commission.

ACTION: Final rule.

SUMMARY: This document amends the rules to provide for reimbursement of out-of-pocket costs incurred by volunteer examiners and volunteer examiner coordinators in connection with administering or coordinating amateur operator license examinations. The rules are necessary so that the volunteers can recover their prudently-incurred expenditures. The effect of this action is to establish regulations which permit reimbursement to volunteers for their necessary expenses.

EFFECTIVE DATE: August 31, 1984.

ADDRESS: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT: Maurice J. DePont, Private Radio Bureau, Washington, D.C. 20554, (202) 632-4964.

Appendix

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended as follows:

See List of Advertisers on page 98

* * * * *

1. Section 97.31(c) is revised to read as follows:

§ 97.31 Volunteer examiner requirements.

* * * * *

(c) Volunteer examiners may not be compensated for services. They may be reimbursed for out-of-pocket expenses, except for Novice class examinations (see § 97.36).

* * * * *

2. Section 97.33 is revised to read as follows:

§ 97.33 Volunteer examiner conduct.

No volunteer examiner shall give or certify any examination by fraudulent means or for monetary or other consideration. Violation of this provision may result in the revocation of the amateur radio station license and the suspension of the amateur radio operator license of the volunteer examiner. This does not preclude a volunteer examiner from accepting reimbursement for out-of-pocket expenses under § 97.36. Reimbursement in any amount in excess of that permitted may result in the sanctions specified herein.

3. New § 97.36 is added as follows:

§97.36 Reimbursement for expenses.

(a) Each volunteer examiner coordinator and each volunteer examiner may be reimbursed by examinees for out-of-pocket expenses incurred in preparing, processing or administering examinations for amateur station operator licenses above the Novice class. The volunteer examiner coordinator or the volunteer examiners must collect the reimbursement fee, if any, from the examinees. No reimbursement may be accepted for preparing, processing or administering Novice class examinations.

(b) The maximum amount of reimbursement is $4.00 for 1984 and will be adjusted annually each January 1 thereafter for changes in the Department of Labor Consumer Price Index. Changes in the maximum amount of reimbursement will be announced by the Commission in a Public Notice. The amount of such reimbursement fee from any examinee for any one examination at a particular session regardless of the number or examination elements taken must not exceed the published maximum.

(c) Each volunteer examiner coordinator and each volunteer examiner who accepts reimbursement must maintain records of out-of-pocket expenses and reimbursements for each examination session. They must certify on or before January 31 of each year to the Commission's office in Gettysburg, PA 17325 that all expenses for the period from January 1 to December 31 of the preceding year for which reimbursement was obtained were necessarily and prudently incurred.

(d) The expense and reimbursement records must be retained by each volunteer examiner coordinator and each volunteer examiner for 3 years and made available to the FCC upon request.

(e) Each volunteer examiner must forward on or before January 15 of each year the certification concerning expenses to the volunteer examiner coordinator who coordinated the efforts of the volunteer examiner and for which reimbursement was received. The volunteer examiner coordinator must forward all such certifications and its own certification concerning expenses to the FCC on or before January 31 of each year.

(f) The volunteer examiner coodinator must disaccredit any volunteer examiner who fails to provide the annual certification. The volunteer examiner coordinator must advise the FCC on January 31 of each year of the volunteer examiners that it has disaccredited for this reason.

4. Section 97.507(e) is revised to read as follows:

§ 97.507 VEC qualifications.

* * * * *

(e) Agree not to accept any compensation from any source for its services as a VEC, except reimbursement for out-of-pocket expenses permitted by § 97.36; and

* * * * *

5. The introductory text preceding paragraph (a) in § 97.515 is revised to read as follows:

§ 97.515 Coordinating volunteer examiners.

A VEC will accredit amateur radio operators licensed by the Federal Communications Commission as volunteer examiners (see § 97.30). A VEC will seek to recruit a broad representation of amateur radio operators to be volunteer examiners. A VEC may not discriminate in accrediting volunteer examiners on the basis of race, sex, religion or national origin. A VEC may not refuse to accredit volunteer examiners on the basis of membership (or lack thereof) in an amateur radio organization. A VEC may not discriminate in accrediting volunteer examiners based upon their accepting or declining to accept reimbursement. A VEC must not accredit an amateur radio operator volunteering to be an examiner if:

SATELLITES

USING THE AO-10 APOGEE PREDICTIONS

Apogee predictions for the month of October are provided for three sections of the United States: Washington DC at 39N 77W, Kansas at 39N 95W, and California at 38N 122W. Times are in UTC and apogee in this case is mean anomaly 128 rounded to the nearest whole hour. Use the chart as a guide in aiming your antenna, then fine-tune the azimuth and elevation values to peak the satellite's beacon signal. If you require more accurate orbital predictions, contact AMSAT at PO Box 27, Washington DC 20044.

AMSAT ANNUAL MEETING

The yearly AMSAT technical symposium and general-membership meeting is slated for Saturday, November 10 at the Amfac (formerly Airport Marina) Hotel on the north side of Los Angeles International Airport. A block of convention-rate rooms has been set aside—for reservations, contact the hotel at (213)-670-8111.

Technical presentations on present and future amateur-satellite projects will be given during the morning and afternoon sessions. The general-membership meeting will be held in the evening following a banquet dinner. For detailed conference information and registration, send an SASE to Dennis Dinga N6DD, PO Box 4111, Diamond Bar CA 91765.

Thanks to Amateur Satellite Report *for this month's news.*

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Let's plunge into some questions this month, which I think are broad enough to apply to a good many of us involved in RTTY.

Rick Thomas of Okemos, Michigan, asks about the use of optoisolators to pick off a signal from a RTTY loop (hmm...nice phrase) for inputting to a computer. Well, Rick, the use of isolating devices between a teleprinter loop, typically running 150 to 300 volts at 60 mA, and the sensitive input of a computer is a very good idea. As you suggest in your letter, optoisolators are one such device which can be used. Fig. 1 is a simple scheme to pick the signal off a loop and output the data through an optoisolator. One feature of this scheme is the use of a bridge rectifier to extract the signal from the loop, thus making the circuit immune to the polarity of the loop.

Another way to derive the RTTY signal but remain isolated electrically from the loop is with the use of a magnetic reed relay. Fig. 2 is a way to interface a reed relay into a loop. In this case, the current limiting on the loop should keep the relay coil from burning out despite being supplied more voltage than is normally used. I would use this type of a circuit if I had to key another loop that didn't use TTL voltage levels.

Rick also expresses concern over lightning-induced voltage transients getting into his loop or equipment. Well, you might take a look at a new little wonder, the metal-oxide varistor. These MOVs look like a disc capacitor but are truly little MORvels, pardon the pun. Radio Shack carries two versions: The V8ZA1 (276-569) protects digital and linear circuits operating at five volts and below, and the V130LA10A (276-570) is for line-operated equipment. Fig. 3 is a simple diagram of how to hook one of these up to a piece of line-operated equipment. It should be relatively easy to adapt this to whatever you like.

Here's a note from Harvey Wenzel KA8CUB in Brunswick, Ohio. Harvey has just gotten hold of a Model 33 ASR Teletype® machine and would like to hook it up. Way to go, Harvey! Unfortunately, a lot depends on just what "guts" your machine has, as different call-control units, that's the circuitry in the panel on the right, require different hookups. However, here's something to gel you started. Look inside of your machine for a nine-conductor screw-type terminal strip. It should be near the back and, if you're lucky, labeled 151411. Now, look at Fig. 4 and try to use these hookups to run your printer and keyboard. Good luck, and if you can determine the exact call-control unit or send me whatever information you can derive, I will see if I can help out.

For years we called them either terminal units or demodulators. Now, they are marketed as receiving interfaces. Still the same thing, folks. That's why this note, from Kris Cena in Hamilton, Ontario, rings a bell. Kris would like to know what the best interface is to go between a receiver and his microcomputer. Kris, you don't want to know what the best interface is because, as the saying goes, if you have to ask, you can't afford it. The bottom line is that about any terminal unit will do just fine, not necessarily one that is directed at the computer crowd. If you are lucky, a pass or two at hamfest tables may turn up just what you need. The essentials should be a stable, preferably fairly-modern unit that is capable of putting out a TTL-level signal. Of course, you could always use one of the isolation circuits from above to adapt a "loop only" bargain. Any of them should work just fine.

Kaypro owners, listen up! We said a few months back that I had seen nothing for that machine. Well, I still haven't but Tyler Parsons WB7DDL says that he has something for you. Tyler is running a RTTY terminal program, written in Pascal, on his Kaypro II. He is offering the program at $29.95, including the program and instructions on disk. He also indicates that he would consider adapting the program for the Kaypro 4 if there is sufficient interest. Write him for more information at 1915 S.E. Stone Street, Corvallis, Oregon 97333, and tell him you are interested in the Kaypro RTTY program mentioned in "RTTY Loop."

Another new member of the club is Harry J. Przekop, Jr. WB9EDP near Chicago, Illinois. Harry is interested in talking to other users of the Drake Theta 7000E communications terminal. Sorry to say, Harry, I have no personal information on this terminal. As I mentioned last month, what information I get, I print. If the manufacturers are interested, I am available. Anyway, if you want to share your experiences with Harry, drop him a line at 332 S. Cuyler, Oak Park, Illinois 60302. Send me a copy, too, and I will share the information with the multitudes!

To those who have written asking where the printouts of the winners of this year's SCATS RTTY art contest are—they didn't send them to me this year. Sorry. Maybe next time?

A letter from Ray Smalley NB2W in South River NJ has me a bit confused. Ray relates that he is "trying to use Clay Abrams' NEWRTTY program on the CoCo* but would like to use the RS-232 port instead of the ROM port." Ray, let's define a few terms, then look at the program. On the back of the CoCo is a four-pin DIN connector, commonly called the RS-232 port. This serial port is not a true, hardware, serial port, but rather a "bit banger" which uses one bit of a parallel port for input, one bit for output, and a software serial-input routine. In some respects, this resembles the RTTY program for the 6800 published here about six or seven years ago. Now, on the side of the CoCo behind a spring-loaded door is an edge connector, commonly called the ROM port. This is, in fact, an extension of the CoCo's address and data bus. Several manufacturers take advantage of this fact by building short extension buses, kind of mini mother boards, which allow several ROMpack-type devices to be plugged in at once.

Now, with that said, let's look at NEWRTTY. This program sends RTTY data out and receives demodulated RTTY data in through the bit-banger RS-232 port. The software driving the port has been changed so that instead of expecting ASCII, it expects Murray and does the necessary conversion before presenting the data to you. So, as you can see, the standard RS-232 port is all you need use with this program; you need never touch the ROM port. Perhaps someday Clay will come up with a disk version of the program, and that ROM port will be needed to run the disk. Hope this clears things up a bit.

Okay east coasters, here we go inundating another amateur. Lowell F. Lind K4AWQ is willing to give away a Model 28 ASR. If it has not been grabbed up by the time this sees print, you might want to drop him a note at 1308 N. Tuckahoe Street, Falls Church, Virginia 22046. Remember that this column is written in July and published in late September if it's gone when you try. No guarantees, I just pass along what I get.

Thanks for the interesting comments and kudos from some more of our readers: Glenn Perry W7RJD, in Mountain Home, Idaho; John A. Kiefer KA6SHT, in Sunnyvale, California; John Sater W3LJW, Union Bridge, Maryland; Alfred Forte III WD4PQN, Ocala, Florida; and Tom Glaza KC8AE, in Filion, Michigan. I appreciate all of your comments and suggestions and shall try to include some of them in future columns.

Quite a potpourri this month. Don't you love the suspense to see what comes next month? Be sure your subscription is current so you won't miss anything in "RTTY Loop."

REVIEW

TEN-TEC MODEL 4229 ANTENNA TUNER

Awhile back, I saw advertised in *73* the Ten-Tec Model 4229 Antenna Tuner kit (Photo A). After some plain and fancy dancing, I managed to snare the checkbook away from the XYL to order it. As I am a rather new ham, she didn't realize the tradition-setting this order entailed.

Despite the slowness of the military mail system, in about three weeks a large box arrived from Sevierville, Tennessee. Only three weeks to get an order from the United States to Guantanamo Bay, Cuba, can be likened to same-day service.

Fortunately, I did not have duty the weekend the kit arrived. So, clearing a space at the dining room table, I carefully opened the box and began. Oops! Look at all those parts! This is a lot different from the few Heathkits® I've assembled in the past. Instant doubt. Did my ambition overload my ability? Did I bite off more than I could chew? (Gasp) Do I need to roust out my Elmer and admit I need help? Tune in tomorrow for the next episode in the exciting adventures of a new ham.

On closer reading of the instruction manual and a calming cup of coffee, I decided to go on until I got stuck and only then yelp for help. The assembly instructions included with the kit said average assembly time was about eight hours. Not being as experienced, knowledgeable, and skillful as the average kit builder, and since I have always relied heavily on the blow-up drawings and pictures in the Heathkit manuals, it took me about 18 hours to complete the kit. Granted, some of this 18 hours involved finding the silly mistakes I'd made and the time it took to regroup. It was my several errors and not the fault of Ten-Tec or the manual.

The roller inductor is pre-wound and formed when the kit arrives. The variable capacitor is the kit builder's assembly project (Photo B). All those stator and rotator plates and spacers! Do NOT lose a spacer! The remainder of the kit's assembly is straightforward. The assembly instructions are more or less divided into sections. Read each section thoroughly before starting. Work slowly and carefully.

Yes, a Novice and a novice kit builder can, with a little thought and a lot of care, assemble this tuner without too much trouble and without the assistance of an Elmer. It may take longer than the eight-hour average of the more experienced

builder, but the results are well worth the time.

Technical Data

The Ten-Tec Model 4229 is an adjustable reactive network used for matching the unbalanced 50-Ohm output of a transmitter to a variety of loads, either balanced or unbalanced. It covers a frequency of 1.8 to 30 MHz, with a dual-range power and swr meter included. Provision is made for selecting between four antennas (Photo C), one of which may be either *longwire*, balanced line, or for bypassing the matching network.

The circuit is a modified L network with an 18-uH silver-plated roller inductor capable of handling 2 kW of rf power. The capacitor voltage rating is 3.5 kV, and the matching-output range is at least 10:1 swr, any phase angle, 1.8 to 30 MHz.

The assembly instructions are well thought out. All of the problems I encountered were because I was careless in reading instructions, I tried to hurry, or I did not pay close attention to what I was doing. Granted the Ten-Tec manual does not have all the pictures and drawings of a Heathkit, but even a kit builder with minimal expertise can assemble a good-looking, functional antenna tuner.

Great, you are saying. This Novice has been rambling on about the assembly manual and how to put it together, but how about after the kit is complete? Then what?

Glad you asked. This is my first experience with Ten-Tec. The operator's manual is well written, nicely laid out, and tells you everything you might need to know about the tuner, the circuits, adjusting the swr/power meter—if it ever needs adjusting—and how and why the tuner works. After talking with other hams at Guantanamo Bay, I found out that the operator's manual is standard Ten-Tec—in other words, high quality.

Unplanned Benefit

An unexpected bonus of using the tuner was that it showed that my ground installation needed work. The ground system I had was not as good as it should have been, which caused arcing between two terminals on the roller assembly. The grounding system adopted consists of a 1k-uF capacitor soldered between the center lead and shield on each end of coax long enough to connect radios, tuners, etc., with a good outside earth ground (see back issues of *73* for details). This solved the arcing problem I had experienced. Properly grounded, the tuner loads nearly everything, and very nicely, too.

Final Remarks

If you already own a "Super Whiz-Bang Automatic Antenna Tuner/Dog Walker/Coffee Maker Deluxe," the Ten-Tec Model 4229 Antenna Tuner kit would make an excellent spare for use during Field Day or emergencies. If you don't own a Super Whiz Bang, etc., and you want a good-looking, functional antenna tuner that you can assemble yourself without the hassles of scrounging parts and without a wallet-smashing cash outlay, try the American-made Ten-Tec Model 4229 Antenna Tuner kit.

Thanks for the photographic processing go to John Howard, President of the GTMO Reflex Photo Club, Guantanamo Bay; thanks also to my Elmer, Tim Miller WB0RXX/KG4TM, who was never too busy to answer my dumb questions.

DOCTOR DX FROM AEA

It was Saturday morning, and the *CQ WW DX* Contest was in full swing. As my wife walked past the shack, she voiced her *familiar "Are you going to be on that* radio all weekend?" complaint. Moments later she remembered that I didn't have an antenna up! Obviously something strange was going on, for the sound of a raging contest was pouring out of the station speaker even though the rig was turned off!

I've been blessed with an understanding mate. I explained that, yes, I would be contesting all day Saturday, and no, I wasn't planning to use a radio—in fact, all of the hams I had been talking with were random bits inside a computer's brain. This, of course, confirmed her earlier assessment of my mental faculties.

Eight hours later I had worked 541 stations in 105 countries and had amassed a total score of 641,125 points. Without a radio.

This was my introduction to Doctor DX, the latest product from AEA. Doctor DX is a contest simulator. It's designed for the Commodore 64 and requires only an external CW key to operate. And I do mean operate!

After plugging the board into the back of your C-64 and powering up, a sleek transceiver is displayed on the screen. The rig features full ham-band coverage (10-160 meters), variable power output, and a digital frequency display. A volume control and bandpass filter are also included. After setting the real-time clock and defining your station's location (more about this in a moment), you are plunged into the incredible world of computer simulation.

The contest is recreated in intricate detail. As in real life, you have the option to either sit on a frequency and call CQ or hunt-and-pounce. In both instances, stations will interact with you during the course of an exchange. Here's an example, where ON7TC is calling CQ on 14.028 MHz:

ON7TC: CQ TEST DE ON7TC K
KK2Y: TC DE KK2Y
ON7TC: KK2Y ??? 14(I missed the report)
KK2Y: RST?
ON7TC: 579 579 BK
KK2Y: R 5NN 05 GL
ON7TC: QSL TU QRZ DE ON7TC

Note that the simulated station responded to my query. Stations will also honor requests to QRS or QRQ and will repeat any part of the exchange that you happen to miss. They will occasionally ask you for a repeat when QRM is heavy or you are sending too fast.

Tuning up and down the band is accomplished by pressing one of four keys on the C-64. The higher end of each band is occupied by slow, inefficient stations. Dropping into the Extra-class segment will allow you to contact super-stations running 30-40 wpm. No sloppy fists here—everyone sends computer-generated code!

Earlier I mentioned the real-time clock. The program uses the time of day and your location in a propagation model that creates the conditions you might expect to hear on the bands. For example, I worked ZL and VK stations on 10 meters early in the morning, and later that afternoon moved to 15 meters, which was open to Europe. During the daylight hours, 80 and 160 meters yielded nothing but static, but excellent DX openings occurred on both of these bands after local sunset. Of course 20 meters was crowded with stateside big guns endlessly pounding out "CQ DX". The model seems to be very realistic and can be verified by comparing Doctor DX's band conditions with the real thing.

Possibly one of the most exciting aspects of Doctor DX is the ability to operate from any location on Earth. As mentioned above, the propagation model uses both time and location to create band conditions. You have the option to define any location you wish by supplying Doctor DX with the appropriate latitude and longitude.

Ever wonder what it's like to live in Burma? Key in 17N, 96E and you are there, experiencing conditions just as they would be if you made the trip. Like to activate Albania? Try 41N, 20E and work the pileups! I took a trip to the Sudan and worked scores of VUs on 160 meters!

Photo. A. Front view of completed kit.

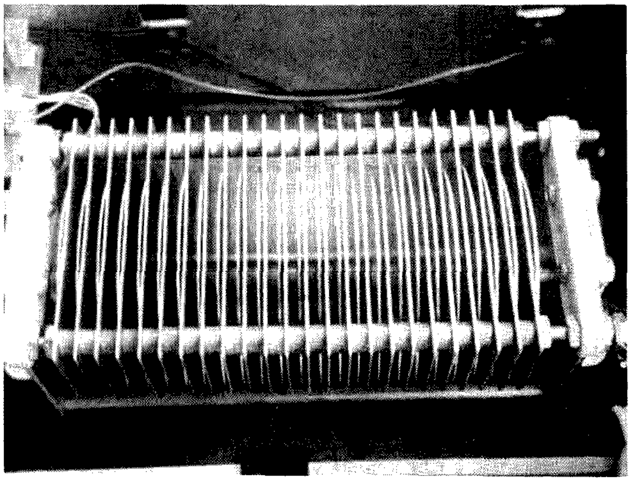

Photo B. Variable capacitor has many parts to assemble.

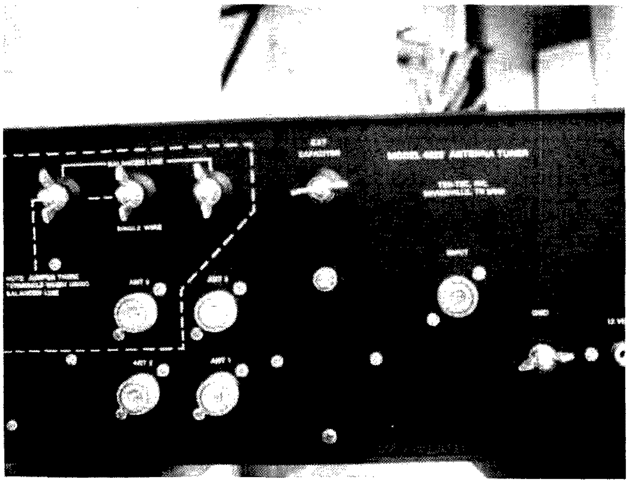

Photo C. Your choice of 3 coax-fed antennas and a longwire or balanced-line antenna.

On-screen scoring information is another outstanding feature. Doctor DX is, after all, a contest simulator/trainer. Complete statistics are displayed in real time and include countries/zones worked per band, aggregate countries/zones worked, number of QSOs, points, and total score. Your contact rate, in QSOs per hour, is also given as an indication of your relative skill—at one point I was clipping along at 136 QSOs per hour while working a string of JAs on 15 meters. This detailed information allows you to compare your operating skill with that of others and to measure the improvement in skill that comes with practice.

You may also use the scoring information to participate in the AEA awards program. As in the real world, you can earn AEA-CC for 100 DX countries worked, AEA-AZ for contacting all 40 zones, 5-band AEA-CC, or be admitted to the AEA Honor Roll for working 250 DX countries or more. A special coding system generates a checksum figure that verifies your achievement—no QSLs are required! In addition, AEA plans to publish a list of the high-scoring stations in their magazine ad each month.

This single program is incentive to buy a C-64. I know it's tough to believe that a piece of software could so realistically simulate amateur radio, but it does. You absolutely must hear it—a few times I caught myself reaching up for a knob to tweak!

I could talk myself blue trying to convince you that this product is the most exciting thing I've seen in my eleven years as a ham, but it isn't the same as experiencing it yourself. My final advice? Buy this program *now!*

For detailed information on Doctor DX, contact *Advanced Electronic Applications, PO Box C-2160, Lynwood WA 98036.*

BILAL ISOTRON 40

When the box arrived in my office last Wednesday, I remember thinking: "Even Ralph Bilal couldn't fit a 40-meter antenna into a package *only* 33" × 6½" × 3"...why, that's smaller than the boxes most model airplanes come in!"

Ralph had promised to send me the latest version of this Isotron 40, a small, versatile antenna designed for limited spaces such as apartments, condos, campers, and the like where it is almost impossible, for either legal or physical reasons, to put up a full-sized antenna. It's also recommended, from the standpoint of size alone, to serve as an emergency, mobile, or portable antenna that can be used in motel rooms, at a disaster site, or even bracketed to the bumper of an automobile.

"All well and good," I thought, "but does it work?"

Unpacking

On Friday, after work, I took the box out of the trunk of my car and carried it into the workshop, wondering if I'd be able to get it on the air before dark. When I opened the box, the first thing I noticed was the neat packaging job done by Bilal. There were two plastic bags containing hardware—good quality, plated hardware or aluminum hardware, depending on the use. I wondered if there was enough to go around; it has been my experience in the past to be shortchanged on nuts, bolts, and washers. But not this time, as you'll see.

Each component or group of components was neatly wrapped and protected with brown paper and packaging tape. There were four pre-drilled and bent aluminum plates, one with an SO-239 UHF connector and a small standoff insulator already mounted on it; there was a 31" length of clear plastic tubing, partly wound with #12 insulated wire, with a nice foot-long lead and terminal soldered in place, and a piece of clear plastic tubing about 20" long, pre-drilled with holes; there were a couple of pieces of Lucite® with holes in them, a piece of 1"-square aluminum tubing, and several other, smaller pieces that I couldn't immediately identify. Nothing elaborate or fancy, either—just plain vanilla—and good old-fashioned workmanship. I began to believe that when Ralph Bilal *told* you something, you had better believe it. My confidence was increasing by the moment.

Assembly

The instructions include diagrams, step-by-step assembly comments, and a final tune-up procedure. After reading and rereading the instructions (something I seldom do because the drawings are clear, but in this case the antenna components seemed so different in size and shape from anything I had ever seen before that I figured that I had better read them carefully), I began the assembly. Surprisingly, it went smoothly and without any problems at all: a new first for me! Everything fit into place and all the holes lined up perfectly with no bending, binding, or mismatches anywhere.

Good heavens! So that's what this thing looks like! (See photo.) I couldn't imagine anything that ever looked less like an antenna! Oh, well, Ralph has been at this for over five years, so I had better trust him. He knows more about *this thing* than I do.

The "far" ends of the parallel rods were pre-drilled to accept typical TV-mounting hardware, and the hardware itself was included: U-bolts, washers, nuts, and plates of good, plated quality. Even the plastic bar had a dowel inserted in one end for reinforcement—the result of experience and cut-and-try engineering.

The instructions suggested mounting the antenna on a short length of 1¼"-diameter TV-mast tubing, and I just happened to have a five-foot length in the garage. I mounted the Isotron "antenna" to the TV mast with the help of my XYL who held things straight while I tightened the clamps. After all was square and aligned, I *did the final tightening of the hex nuts,* and there it was! Clearly, something different.

The weight was negligible and the wind loading laughable. Gosh, this thing could fit on top of almost any chimney bracket, on a mast alongside a trailer, or *even in* the shack in the middle of the floor! Yep, that's what I did. I happened to have a military-surplus wooden tripod that had been used to mount a transit. The short length of TV mast exactly fit into the central collar, so I set it up in the shack (read spare bedroom) between the beds. A ten-foot piece of RG-8/U was enough to reach the operating desk and B&W coaxial switch mounted there.

Tune-Up and Operation

Here is where things usually begin to go very wrong, with my usual luck, and I had little confidence that this ugly duckling would ever be a swan in spite of Ralph Bilal's confidence. Nevertheless, only 45 minutes had elapsed between opening the box and carrying the contraption to my shack...sort of a new record for me. There it sat on its tripod, daring me to fire up the rig and see what would happen. Okay, here goes.

Wow: signals—and quite loud, too! Putting the rig on the lowest possible output power, just enough to get a vswr reading, I was astonished to get a reading of below 2:1, and by careful adjustment of the small, parallel "tuning" plates attached to the upper and lower "diamond" plates, I was able to get a reading of below 1.5:1 at 7025 kHz. That is better than the standard trapped vertical I had been using was able to give me. I switched back and forth between the vertical (roof mounted, with 12 radials) and the Isotron 40, noticing that the QRN was appreciably lower on the Bilal antenna, whereas the received signals were not much if any different in strength. Once again, I was impressed with this little critter. Now if it would only transmit, I'd be happy.

Proof of the Pudding

Rather than timidly call a CQ, I decided to be brave and answer someone else. After all, if he didn't come back to me it wouldn't be my fault—or as disappointing—as if I had called and been found wanting. Okay, let's see...here's a good strong signal at 7031 kHz...KU1G...nice CW... there, he's signing...

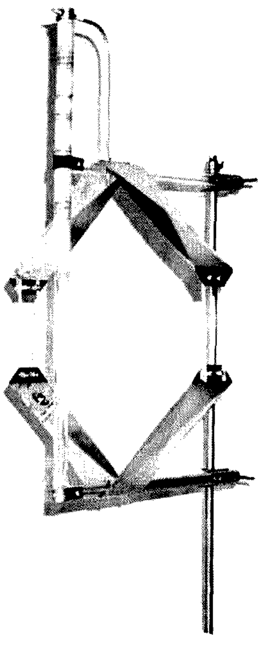
KU1G KU1G, de W1XU, W1XU, K.
W1XU de KU1G; R, R, Tnx call OM; ur sigs 599, 599 hr in Monroe, CT; name is John. Hw copy? $\overline{AR}$. W1XU de KU1G, K.

Wow! 599 in Connecticut! Well, maybe that's just an exception. Let's finish here with John and try another.

At 0020Z (twenty after seven, local time) I heard WX4L calling CQ. A quick shout and he came back: 559 in Gaffney, South Carolina. Name is Ed. Well, that is more reasonable, I thought, but still, all the way to South Carolina on an indoor "lump" ain't too shabby!

Next, I called Steve K4CXJ in Nashville, Tennessee, and we compared antennas. The trapped vertical gave me a 569 with QSB and the Bilal Isotron gave me a 569 with no QSB! The band wasn't great, but it was active.

Along about twenty before 9 I heard Bill K2SVC in Ithaca, New York, and he gave me a 599 with some QSB. A quick comparison showed the outdoor vertical at S9



The Isotron 40.

and the indoor Isotron at S8. Not bad, I'd settle for that any day.

After signing with Bill, I worked Jim KX8E in Highland, Michigan. Jim said I was 599 there and claimed very little if any difference between the vertical and the Isotron. It was obvious that the band was improving and that the mid-range stations were skipping in loudly.

I wonder if I ought to try a "local" to see what happens, I thought. There was Paul KB1MJ/BS with his brand-new Extra-class ticket on 7024 kHz. Giving Paul a quick call, I got a 589 from him. He was down a bit, I thought, but the 569 I gave him was still a good report. When he told me he was running 20 Watts to a home-brew *station* (not just a transmitter), I perked up. It seems that Paul actually loves to build gear, and his receiver is about 9 months along in development...with a few more to go until he is satisfied. The keying was very nice, home-brew, of course, and Paul said he made the paddles, too!

The transmitter was a combined solid-state vfo with a tube final. Nice. I suggested to Paul that when his station was completed to his satisfaction, maybe he ought to write it up for a magazine...hint, hint! Let's hope he does.

Well, it was getting late; maybe a couple more and then to bed. Tuning around, I discovered Frank VE2GG in Dorval, Quebec, on 7021 kHz. He came right back to my call: "599, OM." He was about a 589 at my station. Comparing antennas, Frank mentioned to me that the Isotron was S9+10 dB, whereas the outside antenna was only S9+5 dB! Here, the Isotron actually put out a better signal than the regular antenna! Probably skip angle, etc., but who cares? The performance of the Isotron 40 is just plain phenomenal.

My last QSO of the evening was with Chuck N8FNZ in Detroit. He gave me a 589 and I gave him a 579 at 0354Z, six minutes before eleven o'clock local time. Chuck was using his new Icom 751 and a dipole, sloping toward the east.

Well, time for hitting the sack soon, so I signed with him after a pleasant rag-chew and switched off the rig. Well satisfied with the evening's work, I decided to try SSB on Saturday morning. After all, with 75 Watts *output,* CW is a lot easier to *cut* the mustard than phone, I realized, so phone would be the final proof I needed to see if the isotron was really an antenna.

On Saturday morning at 9:50 local time, I heard W3DWI calling CQ. His signal was loud and I wanted to call him, but I had not changed the setting of the antenna to adjust it for lowest vswr up here on phone. Nevertheless, I decided, what the heck; I'll just call anyway; no harm if he doesn't hear me. A short two-by-two, and Ed in Chambersburg, Pennsylvania, came right back with a 5/7 report...very little QSB... nice steady signal. We exchanged the usual information and had a pleasant half-hour chat right in the midst of the Saturday morning QRM.

When the QSB took me almost out, I switched over to the outside antenna and was able to finish the QSO. So—we found out that under poor conditions, the outside BIG antenna is a bit better than the small (tiny) indoor one. Well, what's so surprising about that? That's what one would expect...but I was still very satisfied with the Isotron 40. Ralph hadn't lied to me yet; he hadn't overstated his performance figures; the antenna worked just as he said it would. Not only that, I firmly believe that if the Isotron 40 were placed at the same height as my vertical and outdoors, it would work equally well! That's a lot to say, but I think it is a true statement...and I'm going to prove it soon.

Later, after a long weekend of testing

the antenna (during which time, nearly 100 stations were worked on phone and CW), a pattern became quite clear: Under good conditions the Isotron 40 nearly equalled the much higher outdoor vertical. Under poor conditons, it was nearly three S-units poorer. On the average, the Isotron was only one to two S-units down compared with the vertical.

It will be desirable to mount the antenna outdoors at the same height as the vertical for further comparisons. I strongly believe, based on tests so far, that it could be almost as effective as the vertical.

Other stations contacted in the US were K4JE (589), W4LRD (579), and W2JUF (579). During the European Field Day, we worked the following foreign stations using the Isotron 40: ON7AR/P (589), G3WKX (589), DL0ET (559), DL0OS (379), DL0AU (559), G4GXK (579), DK0TU (599), DF0CN (599), PI4RT? (599), and GM3USL (599). Later, I heard NQ6E in San Francisco, and Bob gave me a 569. Of course everyone knows that all contest reports are not exact, but at least the antenna can work DX without a terrific disadvantage.

Many times my signal would be S8 on the Bilal antenna and S9 on the vertical. In only one case, reported before, was the Isotron better than the vertical.

Almost every station contacted in the US and Canada was very interested in knowing more about the Isotron. One operator even said he was going to buy the 80-meter version after hearing what the 40-meter version could do. So, there you have it, fans. Try one for yourself and see what *you* think.

Theory of Operation

The Isotron antennas may be capacitive hats on a loading coil . . . because that's what they appear to be electrically. However, there is a large radiating surface (according to Ralph) that would seem to make the Isotron antennas the equivalent *in surface area* to full-size antennas. This does not imply that the "capture area" of the Isotron is the equivalent of the larger antenna, however. In spite of the small size (31" × 18" × 12", approximately), it appears to be radiating quite efficiently—something that I had not thought possible with merely a loading coil with capacity hat as a radiator of rf energy.

The claimed bandwidth between 2:1 vswr limits is 200 kHz, according to Ralph's measurements. I was able to verify this approximately by swinging between roughly 7050 and 7250 kHz without retuning the antenna. However, for really critical work, it would be best to retune the antenna when moving from the low end CW portion to the high end SSB portion of the band.

Ralph mentions the fact that it is necessary to be very careful in adjusting and tuning the antenna because the surroundings can affect its impedance drastically. He gives some good counsel in the instructions about this, and several recommendations to follow in case tuning up is a problem. An rf noise bridge or similar device to help tuning is strongly recommended when setting up the Isotron for best performance.

Other Antennas by Bilal

Ralph Bilal can furnish a 160-meter Isotron, an 80-meter version, and a 20-meter version also. I would like to say that the one that looks most interesting to me is the combination 80/40 Isotron—actually two antennas, tuned to the bands, mounted back-to-back on a single mast, and fed with two separate feedlines. Living as I do in a home that rests in a small clearing in the woods, that would really solve my antenna problem. I have used a chimney mount for several different verticals and small beams, so I think it would be very practical, simple, and nearly ideal in my location to solve the problem with the Isotron system.

Conclusion

I really like the Isotron 40 and am going to be very interested in trying out the other versions to see if they perform as well on their respective bands as this one does on 40 meters. Certainly the price is reasonable, considering what you get: the 160-meter version that stands only 5 feet high and weighs only 12 pounds (smaller than most two-meter beams) for $149.95 plus shipping; the 80-meter version at 4½ feet and 7 pounds at $63.95; the 40-meter at 31 inches and 4 pounds for $52.95, and the 20-meter Isotron, on special sale at $39.95, measuring only 21 inches and weighing in at a mere 3 pounds. Finally, the 15-meter version at 21 inches and 2 pounds, goes for $32.95. All of these must have shipping costs added, varying between $3.50 and $8.50.

The 80/40 "Special" Isotron comes for only $110 plus $8.50 shipping cost, and there are also 15-meter and 10-meter versions for hams, as well as an 11-meter version for CB.

For your own Isotron, whatever it may be, call or write to the *Bilal Company, S.R. 2, Eucha OK 74342; (918)-253-4094*. Tell Ralph that *73* sent you, with a strong recommendation. Reader Service number 477.

BARKER & WILLIAMSON'S AP-10 PORTABLE ANTENNA

Nothing that simple will ever work.

That was my first thought on viewing the Barker & Williamson AP-10 Portable Antenna. I had seen ads in ham publications from B & W but had always just glanced at them.

Now, however, for the first time in 15 years, I was faced with living in an apartment. I had changed jobs and moved from Ohio to Wisconsin, and I discovered that our new apartment complex allowed absolutely no outdoor antennas.

My father (K8MC), a veteran DXer of many seasons, had purchased the B & W antenna for me as a Christmas present. He did his best to convince me that this was better than no antenna at all. I decided to give it a try. It was a either that or face the unpleasant withdrawal symptoms associated with lack of exposure to Morse code.

The antenna had arrived in a neat little box with all of the parts inside. The parts included a 22½-inch whip which telescoped to 57 inches, coils for 10 meters through 40 meters (including 30 meters), a wire counterpoise, coax, and assorted screws and bolts. (*We've heard that the AP-10 will load on 2 and 6 meters without additional hardware. —Ed.*)

Also included was a very clearly written instruction booklet. Then again, the antenna was so simple that the instruction booklet necessarily was very basic and well written.

Assembly time was about 5 minutes and required only a screwdriver and a pair of pliers. To a seasoned DXer and this second-generation ham, it seemed too good to be true.

Not content to wait until I returned to Wisconsin, we put the antenna on the air at my father's old homestead in Ohio. Since the weather was a little nasty outside, we decided to clamp the antenna to a wooden table in the ham shack.

To make a long story short, the antenna worked. It's true we didn't work any exotic country on the first try, but our CQ calls produced solid contacts on 40 meters with hams in several east-coast states.

Since both of us use antenna tuners for all of our antennas, the B & W indoor whip was run through an MFJ tuner with 1000-Watt capacity. The swr was virtually a flat 1.1:1.

Upon arriving back in Wisconsin, I began to have second thoughts about the antenna loading up properly with my Triton 4. After all, that was a rugged antenna tuner we'd used in Ohio. However, my worries evaporated when I tuned the little whip attached to a wooden dresser in the bedroom with my DenTron Jr. Monitor tuner. Swr could be adjusted down to 1.4:1 throughout the CW portion of the 40-meter band. I called CQ and worked stations from Colorado to New York that first evening.

Summoning up all of my courage several evenings later, I attached the 20-meter coil. The swr on this band could be adjusted to 1.1:1, and I worked stations from California to New Hampshire.

Of course, I was very pleased and surprised by this kind of performance from a little indoor whip. In addition, I felt confident this little B & W product would keep me on the air even in the apartment-complex environment.

Needless to say, there are some compromises and shortcomings one faces up to when using this kind of antenna. You can't put out a booming, dominating DX signal, and you don't always get 599 signal reports. In addition, I have not tried the whip on SSB because I work 100% CW. I'm sure the results on voice transmissions would be disappointing with all of those 1-kW (and 5-kW, too, I suspect) signals on the air.

Working with this antenna on CW is very similar to working QRP. It takes a little more effort to hear the incoming signals and a little patience when transmitting, too. However, the proof is in the pudding, and the B & W whip has proved it can keep me on the air. Unless the bands are totally quiet, I can QSO just about any time I want to.

For example, I have worked 30 states on the 40-meter band, including California, Oregon, Utah, and Maine. While signal reports are not always good, the fact still remains that hams in those places actually heard me well enough to QSL.

The 20-meter band has been even better, and I've actually worked a little DX. I have QSL cards from Haiti, France, and the Virgin Islands. I have many more cards from all over the United States.

While I'm not saying the B & W model AP-10 antenna should be considered as a primary station radiator when better gear can be installed, I am saying that it apparently does the job it was designed to do. It keeps hams in my situation on the air. I'm grateful, because I'd hate to face those horrible symptoms of withdrawal brought on by the lack of exposure to Morse code.

For further details, contact *Barker & Williamson, 10 Canal Street, Bristol PA 19007.*

AMATEUR RADIO IN WEST AFRICA

While tuning across 15 meters looking for a clear frequency to call CQ, I overheard the following complaint from a group of W2 DXers: "Have you noticed that there aren't any Africans on the air? There are never any African stations around." I broke in and agreed with their observation that African hams were few and far between. And then I signed my call, C5AAQ!

While those DXers got their wish of working an African station, many other DXers continue to lament the difficulty of working many of the countries on the African continent. A recent conversation with Tom Gregory N4NW gives some of the reasons behind this difficulty. Tom was stationed in the Ivory Coast for a tour of duty with the State Department, and he signed TU2NW during his stay in West Africa. Tom cites two major problems for hams in West Africa: the drought and the instability of many of the military governments in the region.

The drought in the region began more than five years ago. The westerly winds which sweep across the continent from the Indian Ocean seldom bring much rain to the inland areas, which is why the world's largest desert forms the bulk of the land area of these countries. But climatic changes have made the water problem much worse in recent years.

The drought affects amateur radio through the production of hydroelectric power. There isn't any. For many of the countries in the region, including Ivory Coast, Niger, Nigeria, Ghana, and Upper Volta, the lack of rain has run the reservoirs dry, and that means little or no electricity in these countries.

Obviously, the lack of electricity makes amateur radio much more difficult. While many of the families which are wealthy enough to afford ham radio can also af-

ford a gas-driven electric generator, that generator finds more use powering the drinking water distillery and keeping the refrigerator going than handing out QSOs to deserving DXers.

Even when the power is on, the cost of operating a radio can be extremely high in West Africa. When I was last in the region (1978), an American stationed in the region could count on an electricity bill of $500–1000 per month, just for household needs. You can imagine the bill for running a high-powered ham station for several hours a day!

However, the high cost (and frequent unavailability) of electric power is not the only problem facing West African amateurs. Tribal conflicts, political corruption, and staggering economic difficulties contribute to the highly volatile political situation in the region. Military coups and other changes in government are commonplace, and ham radio often loses out.

In the atmosphere of suspicion and intrigue, anyone with sophisticated communications gear, such as a multiband amateur transceiver, might be a threat to the existing government. And amateur radio is probably out of the experience of many of the people making policy decisions in these countries, which simply adds to the suspicion.

Let's look at what happened in Ghana as an example of the problems facing ham radio in the region. During the military coup in 1982, some of the Americans working in Ghana eavesdropped on the action with a Bearcat 250 VHF scanner. Living through a coup is a terrifying experience. Most official forms of news are cut off by one side or the other, and what you do hear is simply what they want you to hear, not necessarily what is actually happening. So this small group of Americans used their scanner to monitor the military and government VHF frequencies.

Unfortunately for ham radio in Ghana, a local African noticed this eavesdropping and reported the incident to the new powers that be. The new government was horrified to hear that someone could listen in on their supposedly-private radio communications and promptly arrested the Americans as spies!

Based on this incident, which really had nothing whatsoever to do with amateur radio, the new government banned all amateur radio in Ghana and confiscated all the rigs! When was the last time you heard a 9G station on the air?

The local amateur-radio club is working to get the ban rescinded, but it is a long, slow process to convince all the appropriate officials that amateur radio is a plus for their country. One amateur, 9G2XX, was a good enough friend of the Chairman of Ghana to get on the air, so perhaps normal ham radio will return to Ghana soon.

Even in countries where amateur radio has not been completely banned, written licenses are hard to come by. While the appropriate officials in the PTT or other telecommunications authority might be agreeable to issuing a license, such a request must also win the approval of the internal security people, a much more difficult task.

Whether this latter group goes under the name of Ministry of the Interior, Internal Affairs, or the Secret Police, their function is the same: keep the present government in power. And permitting unrestricted worldwide communications via ham radio is seldom part of their efforts.

So a person applying for an amateur-radio license in Ghana, Niger, Upper Volta, Benin, etc., will usually find his request sitting on the desk of some official in the Internal Affairs department, probably indefinitely.

Niger is a good example. DXpeditioners Carl and Martha Hansen traveled to Niger in an attempt to activate this hard-to-work country. Tom Gregory happened to be in the country at the same time, but even their combined efforts proved fruitless. Neither party could get the required permission to operate.

On the other hand, as long as no written license is needed, it is possible to get verbal permission to operate. Nobody's job (or head) is on the line (if the ham does turn out to be a spy) if there are no written documents. And ham radio does have great value for emergency and backup communications, especially away from the larger cities. The MARS-like operation of several French stations in Chad is a good example. These "amateur" stations are running health and welfare traffic from outlying military posts back to France. But don't bother to break in; their documentation won't pass ARRL DXCC muster. Unfortunately for DXers, contacts with these amateurs usually do *not* count for DXCC credit.

Working West Africa

So much for the bad news. Fortunately, there is some good news about amateur radio in West Africa. First, the region is ideally suited to excellent propagation. Sticking out into the Atlantic Ocean in the tropical latitudes around the equator, West Africa offers some super radio locations.

Propagation to the States and Europe is top-notch for many hours a day, and even the Japanese come through loud and clear along the all-water long path, around the tip of South America.

Tom Gregory suggests the months of September and October as good times to look for the West Africans. What rain they get inland falls mainly during that time, and electricity supplies are more reliable. Good radio propagation continues through the winter months, if the hydro power hasn't dried up.

As for the best time of day to look for stations in this region, Tom reminds DXers that local time in West Africa is UTC. As with stateside DXers, early-evening local time is when most of the amateurs sit down in front of their rigs. So search out those Africans in the 1600–2200 UTC range.

Tom spent a good deal of time on the lower frequencies, handing out contacts with his Kenwood TS830 and Alpha linear. Using a vertical on 40, Tom had good success working split frequency on 40-meter SSB. 7070 kHz is a good spot to look for the Africans on 40, coupled with a listening frequency between 7150 and 7200. 7167 is an especially good "hole" in the heavy interference in that part of the world. 2300 UTC is a good time to try 40.

75 meters is a difficult band in Africa because of the extensive use of the 3800-kHz band for RTTY and other point-to-point communications in ITU Region 1. Sometimes you can't even hear the static crashes because the interference level is so high! With the recent expansion of the US phone bands, Advanced licensees will get a crack at the 75-meter DX window of 3775–3800. Tom made about 1000 contacts on 75 during his stay as TU2NW.

While 160 meters is not an amateur band in Region 1, many countries have granted operating permission on Top Band. Tom wrangled 160-meter operating privileges, but had little success on the band. Dragging himself out of bed at 5:30 in the morning, Tom slugged it out on 160 to the tune of 5–10 contacts per night. Even the *CQ* Worldwide contest only yielded 6 160-meter QSOs. Tom transmits in the DX window and listens at 1818 kHz.

Tom made about 12,000 contacts during his tour as TU2NW, and he will be missed by those looking to confirm Ivory Coast. Anyone who hasn't yet confirmed their contact with TU2NW can do so through Tom's QSL manager, AK3F. *Do not* send cards to TU2NW through the bureau system. As with many visitors and DXpeditioners, the cards won't arrive in the country until long after the operator has departed. The chances of your bureau card catching up with the operator are very slim. Tom also operated as TU73 during the spring of 1984 (a special callsign granted for WPX contests). If you missed TU2NW, you still can work Ivory Coast. Tom reports that there are about 20 active amateurs in Ivory Coast now, mostly French visitors. Assid TU1BS is one of the more active hams, and TU2JD occasionally runs pileups in English.

DXpeditioners might find some of the rarer countries very difficult to activate for DXCC, but other countries in the region are good DXpedition spots. In Mauritania, for example, Tom got his 5T5NW license in six minutes! Mauritania is somewhat unique in the region in that it only issues amateur-radio licenses to expatriates, not to locals! Other possibilities are Senegal, The Gambia, and Gabon. As with many of the French-speaking countries in the region, a letter written in French has the best chance of gaining a valid license.

For anyone traveling to the area, Tom suggests writing (in French) to the PTT giving the usual information about your operation: passport information, dates, location, rigs, etc. A copy of your stateside license and a couple of photographs are also necessary. A letter from your local Chief of Police attesting to your good character is a valuable addition.

Since many of the amateur licensing authorities in the region work closely with the local amateur-radio club, it would be a good idea to include the local club in your plans. A letter to the radio club at the same time as your letter to the PTT licensing group can help speed your application.

Meanwhile, Tom Gregory is back in Africa, this time stationed in Pretoria, South Africa. He reports that he should be on the air as N4NW/ZS6 by September. Then he expects to take the South African amateur exam to get his own ZS call by the end of the year.

Since Tom's work for the State Department has him traveling around the region, he might show up from another country at any time. In addition to his TU2NW license, Tom holds 5T5NW and J5NW. Current plans call for an operation from Swaziland 3D6 for the *CQ* Worldwide SSB at the end of October.

In addition to the low-band frequencies mentioned above, you can look for Tom around 14155 or 14180, and 21255 or 21280. He runs RTTY with his Commodore 64 computer and he is often found on CW as well.

While in southern Africa, Tom has high hopes of breaking the logjam of amateur licensing in Mozambique. C9 amateurs have been nonexistent since the communist-leaning present government took power. However, recent breaks between the Soviets and Mozambique suggest that some changes might be in the offing.

QSL Manager Wanted

With his change in location, Tom is looking for a new QSL manager to handle his ZS contacts and other operations in the region. Since he keeps his log on a disk with his Commodore 64, a manager with the same computer equipped with a disk drive would be ideal. Tom can then send a floppy disk up once a month for the confirmations. If you are interested in this job, contact Tom Gregory at the Department of State, Pretoria, Washington DC 20520.

Meanwhile, enjoy the good propagation of the fall months. The next few summers are likely to be as lousy for DXing as the summer of '84, so concentrate on working what you can when the bands are open. And look for T32AW from Christmas Island in the Pacific at the end of the month (including *CQ* Worldwide SSB). That's yours truly out there. OSL T32AW via K1RH.

THE DR. DIGITAL POLL

It's hard to judge what interests the typical Dr. Digital reader solely from the mail I receive. Only certain people are motivated to write letters; for most, the process takes too much time or effort. I am going to get around this problem by conducting a poll. While John Edwards' "FUN!" poll revealed some information about the computer habits of amateur-radio operators, it was not specific enough for my needs. So grab a pencil and answer the following questions.

Send your responses to the address listed at the top of this column. You may keep your responses anonymous.

1) Which microcomputer(s), if any, do you own?

a) Apple
b) Atari
c) Commodore
d) Epson
e) Franklin
f) IBM PC
g) Osborne
h) TRS-80
i) S-100 (IEEE-696)
j) Other

2) Which computer language(s) are you *proficient* in?

a) Assembly language
b) Ada
c) Basic
d) C
e) COBOL
f) Forth
g) LISP
h) Pascal
i) PL/I
j) Other

3) Do you have any experience with mini- or mainframe computers?

a) Yes
b) No

RESPONSE FORM

Read each question and mark your response by circling the appropriate letter next to the number of the question.

1) a b c d e f g h i j	6) a b c d e	11) a b	16) a b	21) a b c d e
2) a b c d e f g h i j	7) a b c d	12) a b	17) a b	22) a b
3) a b	8) a b	13) a b	18) a b	23) a b
4) a b c d e f g h	9) a b	14) a b	19) a b	24) a b
5) a b c d	10) a b	15) a b	20) a b	25) a b c
				26) a b

Comments: ______________________________

4) What amateur-radio applications do you have for your computer?
- a) RTTY
- b) Control of amateur-radio equipment
- c) Record keeping (logs, contests, DXCC list, etc.)
- d) Number crunching (filter design, coordinate calculations, etc.)
- e) Satellite tracking
- f) Morse-code training
- g) SSTV
- h) Other

5) If you use computerized RTTY, which mode(s) do you use?
- a) Murray or Baudot
- b) ASCII
- c) AMTOR
- d) CITOR

6) How much have you spent on computer equipment?
- a) Under $500
- b) $500 to $1499
- c) $1500 to $2999
- d) $3000 to $5000
- e) Over $5000

7) What percentage of your computer programming is done in assembly language?
- a) None
- b) Under 33%
- c) Between 33% and 66%
- d) Over 66%

8) Have you ever built any computer hardware?
- a) Yes
- b) No

9) Have you ever designed any computer hardware?
- a) Yes
- b) No

10) Have you ever made any repairs or modifications to your computer system?
- a) Yes
- b) No

11) Do you own any computer test equipment (i.e., logic probes, scopes, etc.)?
- a) Yes
- b) No

12) To which hobby do you devote more time?
- a) Computers
- b) Amateur radio

13) Do you belong to a computer club?
- a) Yes
- b) No

14) Do you belong to an amateur-radio club?
- a) Yes
- b) No

15) Are you in favor of a digital-class license in the United States?
- a) Yes
- b) No

16) Which hobby have you been involved with longer?
- a) Amateur radio
- b) Computers

17) Do you own a modem?
- a) Yes
- b) No

18) Have you ever used a data base program, such as dBase II, for amateur-radio purposes?
- a) Yes
- b) No

19) If you had to choose only one hobby, which would you pick?
- a) Amateur radio
- b) Computers

20) Are you planning on purchasing more computer equipment in the near future?
- a) Yes
- b) No

21) What is your age?
- a) 15 or below
- b) 16–21
- c) 22–39
- d) 40–59
- e) 60 or above

22) Have you ever written any amateur-radio computer software?
- a) Yes
- b) No

23) Have you ever purchased any amateur-radio computer software?
- a) Yes
- b) No

24) Do you own a microprocessor-controlled rig?
- a) Yes
- b) No

25) What would you like to see emphasized in this column?
- a) Hardware
- b) Software
- c) Equal empasis on both

26) Have you ever used a packet repeater?
- a) Yes
- b) No

Feel free to add any additional thoughts or comments. It is hoped that the information I receive will assist me in choosing topics for the column.

ANOTHER APPROACH TO COMPUTER INTERFACING

Whenever I discuss computer-to-amateur-radio interfacing, I always assume that the reader has a computer with a programmable parallel port or some TTL output lines available. Many computers, however, have only an RS-232 serial port available. This type of port is meant to carry ASCII data and is not suited to control devices.

To get around this problem, a number of companies have developed serial I/O controllers. These devices interpret certain ASCII characters from a serial port and use them to control relays or other switching devices. With a serial I/O controller, for example, a TRS-100 can be used to control electronic equipment without an extra I/O port.

One serial I/O controller is the Sias Engineering CIP/35. This device will interface to any computer that has an RS-232 port. Using certain ASCII characters, the host computer can switch any one of eight relay-controlled outputs on or off. The CIP/35 also has eight inputs that can be read through the serial port.

A controller such as the CIP/35 has some interesting uses. If, for example, a CIP/35 is used to control a repeater, it can be connected with an auto-answer modem to a phone line. The computer does not have to be located at the same site as the controller. This way, one does not have to dedicate a computer for control purposes.

Each output on the CIP/35 can handle 6 Amps. The eight inputs are optically isolated from the board. For more information on the CIP/35, contact Sias Engineering, Inc., R.R. 1, Box 315, Salina, Kansas 67401; (913)-823-8027.

TIPS ON CHIPS

A good way to learn digital electronics is to learn about the various types of digital integrated circuits on the market. Every manufacturer of integrated circuits publishes spec sheets and data books describing their product line. These publications, which are usually available at modest cost, contain a great deal of useful information.

One reference which I use often is the National Semiconductor *Databook*. This publication lists many types of digital logic circuits ranging from simple NAND gates to complex multiplexers and shift registers. Chips are described using pinout diagrams, truth tables, timing diagrams, logical equations, and electrical characteristics. Applications notes are also given. For more information on this *Databook*, as well as other publications from National Semiconductor, contact National Semiconductor Corporation, 2900 Semiconductor Drive, Santa Clara, California 95051.

Some other companies that have low-cost publications available are: Intel Corporation, 3065 Bowers Avenue, Santa Clara, California 95051; Rockwell International, Electronic Devices Division, 1842 Reynolds, Irvine, California 92626. When writing to these companies, ask for their "literature guide." Intel and Rockwell also have many free publications available. These, too, are listed in their literature guides.

NEW PRODUCTS

LARSEN NMO ANTENNAS, PO-K MOUNTING KITS

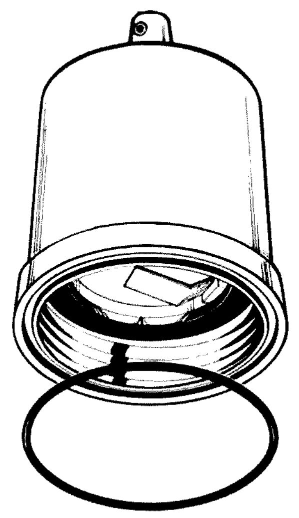
The Larsen PO-K mounting kit features SO-239-style mounting hardware that can be installed entirely from outside the vehicle. The PO series mount looks like the SO-239 connector (sometimes called a female UHF connector), but unlike the SO-239, it can be installed from outside the vehicle. Its two O rings and one gasket offer super moisture sealing.

Larsen's PO-K includes complete mounting kit and coax; the PO-B contains mounting hardware only.

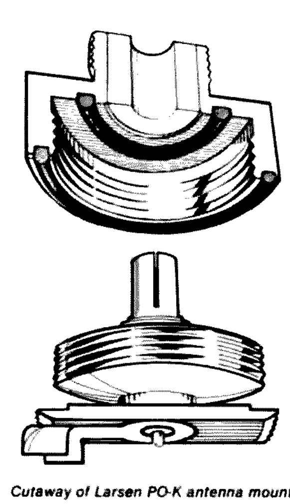
Larsen NMO series antennas offer improved weather protection. The improved NMO coil features an extra lip around the bottom, providing a place for an O ring. The ring surrounds the threads that tighten to the vehicle surface, eliminating the chance that water may be drawn through the threads and decrease performance or corrode mounting hardware.

All NMO series VHF and UHF products now include this change. LM and NLA series are equipped with a neoprene gasket around mounting hardware for a weather-tight seal.

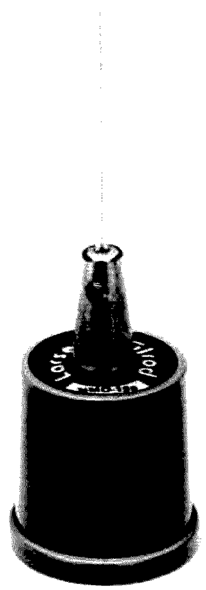
For more information, contact *Larsen Electronics, PO Box 1799, Vancouver WA 98668; (206)-573-2722.* Reader Service number 482.



Larsen NMO antenna base and weather-sealing O ring.



Cutaway of Larsen PO-K antenna mount.



A Larsen NMO antenna.

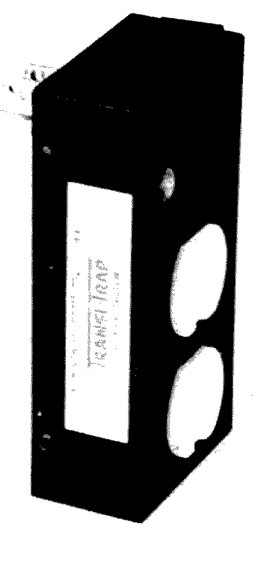
ANTUNER AND HAM-ANTUNER

J. L. Industries has introduced Antuner, an automatic antenna tuner with no moving parts. Antuner covers a wide spectrum of frequencies from .1 MHz to 100 MHz. An antenna system with Antuner in which 50 feet of wire is attached to the hot end of the unit and a minimum of 25 feet is attached to the ground side of the unit will produce an swr of no higher than 1.5 to 1. For frequencies above 12 MHz, it rarely exceeds 1.2 to 1.

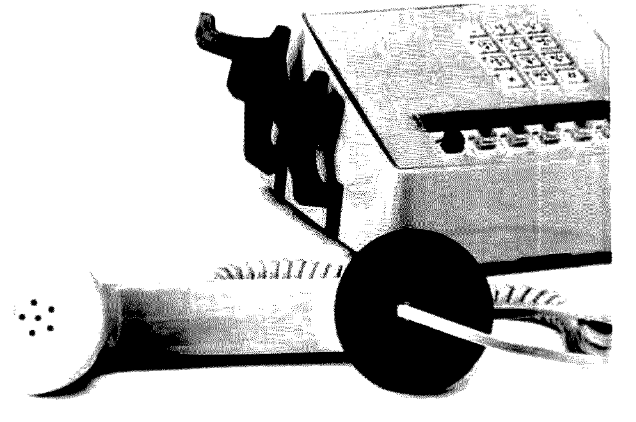
To achieve these results, Antuner incorporates the use of sophisticated circuitry for tuning as well as input-impedance stabilization. All this is accomplished by the use of a three-port circulator. The system is phased so that there is minimal attenuation in the feed direction and a much greater attenuation in the reverse direction. Currents in the feed direction induce currents in the windings that are in phase, while currents in the reverse direction induce currents that are out of phase. A wideband instantaneous antenna tuner without moving parts is the result. Completely passive, it is an efficient coupling system for an asymmetrical dipole antenna. If desired, a longwire could be connected to the hot end of Antuner and a good ground to the ground side of Antuner. Antuner can be used for marine installations (sailboats and commercial ships), oil rigs, ham radio for airplanes, and for special situations in which unobtrusive horizontal antennas are needed.

The Antuner can handle 1000 Watts PEP. A 300-Watt version, called the Ham-Antuner, is also available.

For more information, contact *J. L. Industries, PO Box 547, Hallandale FL 33009; (305)-458-6094.* Reader Service number 481.



The Transi-Trap surge protector from Alpha Delta Communications, Inc.



The Black Jack portable modular-telephone jack attachment for computer telecommunications.

SURGE PROTECTOR FROM ALPHA DELTA

The new Alpha Delta Communications, Inc., Model ACTT ac Transi-Trap™ is a direct plug-in-the-wall ac surge protector which includes two 120-V-ac sockets, status light, circuit breaker, and a unique 3-stage automatic surge-protection circuit.

The Model ACTT provides both transverse- and common-mode protection with a hot-to-neutral, neutral-to-ground, and hot-to-ground 6000-volt, 2000-Amp surge discharge self-restoring high-speed circuit. (Several typical competitive devices use only a single-stage, 100-Amp protector.)

The configuration of the Model ACTT also protects equipment plugged into any other common-branch ac wall outlet down line from the ACTT.

The unit is UL listed and is available at Alpha Delta dealers or direct from the manufacturer.

For more details, contact *Alpha Delta Communications, Inc., PO Box 571, Centerville OH 45459; (513)-435-4772.* Reader Service number 478.

PORTABLE MODULAR JACK FOR MODEMS

The Microperipheral Corporation has announced a new portable modular-telephone jack attachment for computer telecommunications. The product is marketed under the trade name Black Jack™.

The Black Jack solves telephone and computer interface problems encountered by growing numbers of portable-computer owners and direct-connect modem users. Most hotels, offices, and other locations from which computerized telecommunications are desirable and necessary do not have modular (RJ11C) jacks. Unless special equipment is installed or the bulky old-fashioned carbon acoustical coupler cups are used, telecommunications are not an option from many locations.

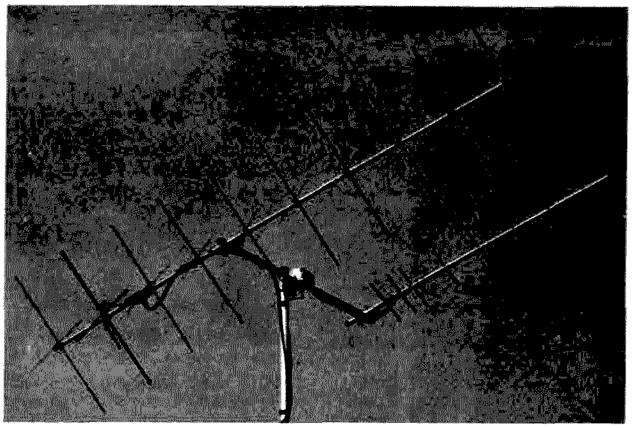
The Black Jack is constructed of rubber with a built-in circuit card and modular jack. Its unique connectors make it compatible with single- or multi-line telephone handsets such as those manufactured by Bell, ITT, and GTE. The unit requires no power. Modems equipped with touch-tone™ dialing may dial directly through the Black Jack. Pulse dialing is accomplished on the telephone set itself.

In addition to solving the problems associated with hard-wired telephones lacking modular jacks, the Black Jack eliminates the loss of line sensitivity associated with the use of acoustical couplers. The new direct-connect modems result in sensitivity gains of approximately 20 dB over the old-fashioned acoustical couplings. The Black Jack lets the modem user keep these line-sensitivity gains while improving telecommunications performance.

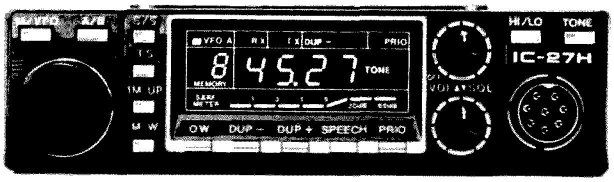
For additional information, contact *The Microperipheral Corporation, 2565 152nd Avenue NE, Redmond WA 98052; (206)-881-7544.* Reader Service number 483.

HAMTRONICS OUTDOOR SCANNER ANTENNA

Hamtronics, Inc., a manufacturer of low-noise receiving equipment for amateur radio, has announced a new antenna for scanner and monitor buffs to serve a need for a scanner antenna which is halfway between a built-in whip on a scanner and a large outdoor antenna requiring roof mounting with some sort of mast arrangement. Hamtronics has designed a compact "Power Antenna" which may be installed easily on the side of a house, outside a window, in an attic, etc., without any special mast or brackets.



Cushcraft's new amateur satellite antenna system.



The IC-27H 2-meter mobile transceiver from Icom.

The ACT-1 Power Antenna is a broadband whip antenna with a low-noise preamplifier in its base. Although much smaller than a full-size outdoor antenna (25 inches tall), it provides good coverage of distant signals and is capable of outperforming larger antennas because of the active booster amplifier. The built-in preamp has a gain of up to 15 dB.

A low-noise microwave transistor in the preamp covers from 30 MHz through the new 800-MHz band, and it covers low-band, high-band, and UHF. It is a good outdoor antenna for the 800-MHz band. The problem of large losses in the coax cable is solved by the amplifying of the weak signal from the antenna before the coax cable run can degrade it. There is a benefit from this effect even on UHF and VHF reception. In this regard, the ACT-1 can outperform an outdoor antenna with a separate preamp at the radio.

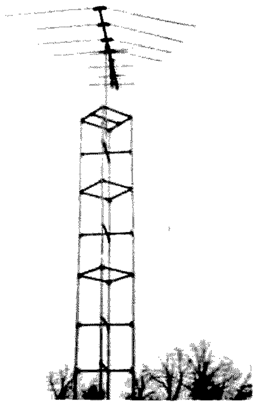
The simple installation required for an ACT-1 antenna and the fact that it is shipped fully assembled make it easy to improve on the performance of radio-mounted whips. Four wood screws mount it to any flat vertical surface. The 50-foot cable plugs directly into the "antenna" and "12-V" jacks on the rear of most scanner radios. If your particular scanner doesn't have a 12-V terminal, a simple 12-V-dc plug-in adapter is available.

For more information, contact *Hamtronics, Inc., 65-F Moul Road, Hilton NY 14468-9535; (716)-392-9430.* A complete catalog is also available for purchase. Reader Service number 485.

CUSHCRAFT SATELLITE ANTENNA SYSTEM

Cushcraft has introduced a new complete amateur satellite antenna system featuring two high-gain, circularly-polarized yagi antennas. The 70-cm, 16-element uplink and 2-meter, 20-element downlink antennas are fixed to a common mounting boom. The entire array is lightweight with reasonable dimensions for quick installation.

For more information, contact *Cushcraft Corporation, PO Box 4680, Manchester NH 03108; (603)-627-7877; telex 953050 Cushsig Man.* Reader Service number 480.



An antenna tower constructed with FrameMaker clamps.

BUILD YOUR OWN TOWER WITH FRAMEMAKER CLAMPS

Build a sturdy, professional-looking tower for a TV, CB, or ham-radio antenna out of common 3/4-inch electrical conduit and plated-steel FrameMaker Clamps.

The only tools needed are a hacksaw (or tube cutter) to cut the conduit and a couple of wrenches. Conduit sections are simply placed into the openings of the clamps, and the plated nuts and bolts are tightened, locking the clamp jaws securely around the conduit.

To avoid the pitfalls of "one-clamp-does-all" designs, several kinds of FrameMaker clamps are made: 4-way fixed and adjustable, 3-way T, 2-way adjustable, and parallel. No locking collars or set screws are needed to prevent slippage. Unlike towers whose joints are welded or brazed, a tower made with FrameMaker clamps can easily be taken down, and the clamps and conduit can be used to build any number of other projects.

Free project idea brochure is available from *Bullseye Products, Dept. DY, 28506 Hayes, Roseville MI 48066.* Reader Service number 479.

IC-27H

Icom has introduced another in its line of ultra-compact mobiles: the IC-27H 45-Watt, 2-meter mobile transceiver.

Standard features include compact size (1-5/8"H × 5-1/2"W × 9-3/8"D), built-in internal speaker for easy mounting, nine full-function memories, 32 built-in PL™ frequencies, IC-HM23 DTMF microphone with up/down scan buttons, three scanning functions (memory scan, band scan, and priority scan), internal lithium-battery memory backup to maintain memories for up to five years, and the IC-MB27 mobile mount.

A variety of options are also available, including an IC-UT16 speech synthesizer and IC-SP4 and SP5 external speakers.

For more information, contact *Icom America, Inc., 2112 116th Ave. NE, Bellevue WA 98004.* Reader Service number 486.

ANTENNA DESIGN SOFTWARE

Smith Software Systems has released their latest ham-related software package for the Apple II+ and IIe computers. Antenna Design Software is a menu-driven program composed of twenty-six submodules to help in the design of HF/VHF/UHF antennas and transmission lines.

Capabilities include design of antenna types such as dipole, folded dipole, vertical, longwire, 2- and 3-element quad, parabolic dish, and loop. Help is also provided with calculating feedline losses, phasing lines, transmission-line transformers, and swr. There are also several related topics such as propagation and component design.

The package was developed with the newcomer to ham radio and computers in mind, but it will be an excellent asset to the expert in helping with long and tedious calculations. The package includes a diskette (not copy protected) and an extensive user's manual.

For additional information, contact *Smith Software Systems, 3767 Cold Spring Creamery Road, Doylestown PA 18901.* Reader Service number 464.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atoo NJ 08004

COLUMBUS DAY INTERNATIONAL DX CONTEST
Starts: 1200 GMT October 13
Ends: 2400 GMT October 14

The first DX contest in commemoration of Columbus Day will be sponsored by the Miami Havana Lions Club. The official contest operators will identify themselves with their QRA, callsign, and with their official number as contest operators. Suggested frequencies will be US amateur bands in 10, 15, 20, 40, and 80 meters, phone and CW.

An amateur station making five contacts with official radio-club DX member operators during the two days will be eligible to apply for the Miami Havana Lions Club QSL Award. Contacts with official operators must be made during the contest period, exchanging RS(T) and QTH. English, Spanish, and Portuguese languages will be used.

SWLs may also apply for this award on a heard basis. Send QSLs or log along with $2.00 in US funds or 6 IRCs for this special award to: Miami Havana Lions Club, Columbus Day International DX Contest, Box 674, Miami FL 33155.

At the start of the contest, members of the contest committee will read the names and assigned numbers of the official operators on the following frequencies: 7230, 14250, 21250, and 28915.

RIO CW DX PARTY
Starts: 1500 GMT October 13
Ends: 1500 GMT October 14

Sponsored by the Pica-Pau Carioca (Rio Woodpeckers CW Group), PO Box 2673, 20001 Rio de Janeiro, RJ, Brazil (with the cooperation of all other Brazilian CW groups). The purpose is to promote 2-way CW contacts between Brazilian and DX stations, enabling DX stations to obtain QSLs valid for several Brazilian Awards. The event is held twice each year on the last full weekend in March and the second full weekend in October.

The general call is "CQ RIO DX PTY". Use all HF amateur bands within your own station-license authority. Exchange RST, name and QTH. There are no logs, but quick QSLing (via bureau or direct) is essential.

Reference frequencies are as follows: 3510/3520, 7020/7030, 14030/14050, 21030/21050, 21130/21150, and 28030/28050.

OREGON QSO PARTY
1700 GMT October 13
to 0800 GMT October 14
1500 GMT October 14
to 0000 GMT October 15

The Hermiston Amateur Radio Club invites all amateurs to participate in the Oregon QSO Party. Each station may be worked once per band and once per mode. Crossband and crossmode contacts are not permitted.

EXCHANGE:

Signal report and state, province, country, or OR county.

FREQUENCIES:

Phone—1810, 3929, 7260, 14300, 21370, and 28600; CW—60 kHz up from bottom of each Novice band; VHF—contacts on simplex only, excluding 146.52.

SCORING:

Count one point per QSO. OR stations multiply QSO points by the sum of states, provinces, countries, and OR counties. All others multiply by the sum of OR counties worked (36 maximum).

ENTRIES AND AWARDS:

All entries must have a log and summary sheet, and if more than 200 contacts are made, a dupe sheet should be included. Entries may be disqualified if logs are incomplete or too many errors are detected. You must sign the summary sheet stating that you observed all the rules. You may photocopy log and dupe sheets or you may obtain extras from the HARC (please send SASE). Logs must be received by November 12th and should be addressed to the Hermiston Amateur Radio Club, PO Box 962, Hermiston OR 97838. Include a large SASE for a copy of the results.

RHODE ISLAND QSO PARTY
1700 GMT October 13
to 0500 GMT October 14
1300 GMT October 14
to 0100 GMT October 15

This contest is sponsored by the East Bay Amateur Wireless Association. RI stations work other RI stations and the rest of the world. All others work only RI stations. The same station may be worked twice on each band: once on phone and once on CW.

EXCHANGE:

RS(T) and state, province, country, or RI city.

FREQUENCIES:

Phone—3900, 7260, 14300, 21360, 28600, 50.110, 144.2, and 146.52; CW—1810, 3550, 3710, 7050, 7110, 14060, 21050, 21110, 28050, and 28110. Use FM simplex; no repeaters.

SCORING:

All stations score 2 points per phone QSO, 3 points per CW QSO, and 5 points for QSOs with Novices and Technicians. RI stations multiply QSO points by the number of states, provinces, and countries worked. Others multiply total QSO points by the number of different RI cities and towns worked (39 maximum).

AWARDS:

Certificates awarded to top-scoring station in each state, province, country, and RI county; plus top-scoring Novice and Technician in RI and out of state. There will also be a certificate for the top RI multi-operator station.

ENTRIES:

Logs must show date/time in GMT, call, exchange, band, and mode. Include your name, call, mailing address, club affiliation if any, total QSO points, multipliers claimed, and final score. Entries must be postmarked no later than November 15th and should be sent to East Bay Amateur Wireless Association, PO Box 392, Warren RI 02885. Include an SASE for results.

MARYLAND-DISTRICT OF COLUMBIA QSO PARTY
Starts: 1800 GMT October 13
Ends: 2100 GMT October 14

Sponsored by the Columbia Amateur Radio Association, the contest is open to all single-operator stations. The same station may be worked on each band and mode.

EXCHANGE:

QSO number; RS(T); and state, province, country, or MD county. Remember that Baltimore and Washington are independent cities!

SCORING:

MDC stations multiply total QSOs by sum of MD counties, states, provinces, and countries. Others multiply MDC QSO total by number of MD counties and independent cities (25 maximum). Also, multiply score by 1.5 if running 200 Watts or less.

FREQUENCIES:

Phone—3950, 7250, 14290, 21390, and 28590; CW—60 kHz up from low end; Novice—3720, 7120, 21120, and 28120.

AWARDS AND ENTRIES:

Maintain a continuous log for phone and CW, but indicate on entry which category (phone, CW, or mixed) you are entering. Certificates for top scorers in each category will be awarded. Mail logs, dupe sheets (for over 200 contacts), and summary by November 30th to CARA, c/o Robert K. Nauman WA3VUQ, 4017 Font Hill Drive, Ellicott City MD 21043.

JAMBOREE ON THE AIR
0001 Local Time October 20
to 2400 Local Time October 21

JOTA is Scouting's annual ham-radio event, held during the third weekend of October. This is the 27th year it has been held, with thousands of stations around the globe participating. If propagation is right, it is common to work Scouting DXCC. In past JOTAs, Scouts in some remote areas like Antarctica, Ascension Island, Christmas Island, Gough, and Seychelles were heard.

In the USA, many Scout Councils and Districts hold camporees to coincide with JOTA. Hams set up Field-Day-type operations, giving campers a chance to exchange greetings with Scouts everywhere.

Generally, the exchanges include typical information like name, QTH, Scout rank, hobbies, etc., with some leading to long-lasting pen-pal friendships and the exchange of photos, badges, and patches. SSTV and ATV give some a chance to have a "look-see" at the other guy. Other QSOs reported were via RTTY, EME, and even OSCAR.

Look for K2BSA (the BSA Headquarters station in Dallas TX), HB9S (the World Scout Headquarters in Switzerland), and for other special callsigns from many countries.

Boy Scouts and Girl Scouts of all ages, Scouters, former members, ham-radio operators, and anyone interested in doing a good turn for Scouting and ham radio are invited to participate. The contest period is given in local time, though some activity flops over from Friday to Monday to take advantage of DX time differences.

Suggested frequencies are 3590, 7030, 14070, 21140, and 28190 on CW; 3940, 7290, 14290, 21360 and 28990 on phone; RTTY, SSTV, and ATV on usual frequencies. Check the Novice frequencies and please move off these calling frequencies to avoid QRM.

No reports in the form of logs are necessary, this is really not a contest. Exchanges should be relaxed and relate to Scouting and ham radio as much as possible. Brief reports, however, are appreciated, giving Scout unit numbers, ham calls used and heard/worked, numbers of participants, interesting incidents and exchanges, etc. Photos with captions especially welcome for the BSA report to the World Bureau. Send them to JOTA Coordinator W2GND, 216 Maxwell Ave., Hightstown NJ 08520.

Radio amateurs are encouraged to invite Scouts or even Scout units to their shacks. If you do not know any, contact your local Scout office for the name of the unit leader in your area. You or your radio club may volunteer to participate in a district or council camporee that weekend. Phone books list council offices as Boy Scouts of America. Call "CQ Jamboree" or respond to such calls and observe all FCC regulations. Consider a fox hunt for more fun.

If you are not a ham or do not have one in your unit, contact one in your area for

CALENDAR

Oct 6–7	ARRL QSO Party—CW

help. If you need help finding one, contact Leo Kluger, American Radio Relay League, 225 Main St., Newington CT 06111. Make reports as indicated above, coordinating with your ham helper.

Certificate cards the size of a postcard are available to anyone participating in any way. They may be ordered beforehand for presentation during JOTA or they may be awarded at Scout or club meetings later. Send requests to Jamboree On The Air, 1325 Walnut Hill, Irving TX 75062, along with an SASE large enough to hold the cards ordered. Affix postage at 20 cents for the first 20 cards and 17 cents for each 8 cards thereafter.

A temporary insignia to wear on the Scout uniform or on jackets is available at $1.25 from the TX address above. Separate orders for certificates and patches will get them to you faster.

The World Scout Bureau, sponsor of JOTA, holds a QSL card contest with 5 prizes for the best handmade cards and 5 prizes for the best printed cards. Entries must be designed by registered Scouts (boy or girl) 18 years of age or less. They must be in standard postcard size and be marked on the back with name, age, Scout unit, and full home address (include USA). Send entries to JOTA QSL Contest, World Scout Bureau, PO Box 78, 1211 Geneva 4, Switzerland. They must be received by December 31st and entries will not be returned. Winners will be notified by March 31st. It would help if radio amateurs would suggest ideas about QSL-card design, including Scout and ham-radio cartoons, etc.

WORKED ALL Y2 CONTEST
Starts: 1500: GMT October 20
Ends: 1500 GMT October 21

The Radioclub of the German Democratic Republic (RKDDR) is pleased to invite radio amateurs all over the world to participate in and commemorate the anniversary of the founding of the German Democratic Republic. Operating sections include single- and multi-operator stations as well as SWLs. Each Y2 station may be worked once per band on phone and once per band on CW.

EXCHANGE:

RS(T) plus serial number starting at 001. Y2 stations will send a two-digit number of "Kreiskenner" instead of a QSO number.

FREQUENCIES:

Use all amateur bands, 3.5 thru 28 MHz, with the first 10 and last 25 kHz of the 3.5- and 14-MHz bands to remain contest-free.

SCORING:

Count 3 points per Y2 QSO. Multiplier is the sum of the number of different Y2 districts worked on each band (maximum of 15 per band). The districts are indicated by the last letter of the call. Final score is the sum of QSO points multiplied by the total multiplier.

SWLs count 1 point on phone and 3 points on CW for each Y2 call with sent RS(T), 2-digit number, and call of station worked with the Y2.

AWARDS:

Certificates awarded to the leading stations in each section of each country.

ENTRIES:

Separated logs are required for each band. Summary sheet showing multiplier and QSO worked on each band also required. Each log must be accompanied by the following signed and dated declaration: "I declare that my station was operated in accordance with the rules of the contest, and in accordance with the requirements of my amateur-radio license." Logs should be mailed within 30 days following the contest to: Y2 Contest Bureau, RKDDR, Hosemannstr. 14, DDR 1055 Berlin, German Democratic Republic. In the case of any dispute, the decision of the Y2 Contest Bureau shall be final. Applications for awards issued by the RKDDR fulfilled in the contest may be sent together with the contest log and indicated fee.

CLARA AC-DC CONTEST
Starts: 1800 GMT October 20
Ends: 1800 GMT October 21

Sponsored by the Canadian Ladies Amateur Radio Association, the Ac-Dc Contest is open to all YL and OM amateurs. Each station may be worked twice, either once on CW and once on phone, or on two different bands.

EXCHANGE:

Signal reports, QTH, and name. Bonus stations will be operating and will identify as such. Each bonus station may be worked twice, once on CW and once on phone, but it *must* be on different bands.

FREQUENCIES:

Phone—3900, 3775, 7150, 14280, 14160, 21300, 28588, and 28488; CW—3690, 7035, 14035, 21035, and 28035.

SCORING:

CLARA members score 1 point per contact with nonmembers, 2 points per CLARA-member contact, and 3 points per bonus station. Multiply by two for contacts made on CW. Multiply total of the above by the number of Canadian provinces/territories worked for total score. Non-CLARA members count points the same except only CLARA-member contacts are to be counted.

AWARDS:

First-place CLARA cup and certificate to first-place CLARA winner, certificates to second and third. Plaque and certificate to first-place non-CLARA winner, certificates to second and third.

ENTRIES:

All logs submitted are eligible for the mini prize drawing. Mail all logs and scores with your name, call, address, and postal code by December 15th to: Muriel Folsy VE7LQH, RR #1, Pender Island, BC, Canada V0N 2M0.

✓ See List of Advertisers on page 98

73 INTERNATIONAL

from page 60

classes: A, up to 1 kW; B, up to 250 W, and C, up to 100 W. All stations may be either fixed, mobiles, or portables and of three other categories: land, maritime, or airborne. Operators are classified as belonging to any of three categories:

- Superior: able to operate class A stations on all authorized bands.
- *Intermedia:* authorized to operate class B stations on 160, 80, 40, 10, 6, and 2 meters, and in the portions 14.000 to 14.200 and 21.000 to 21.250 MHz.
- Novicio: authorized to operate class C stations in 160, 80, 6, and 2 meters, and in the portion 7.100 to 7.150 MHz.

It is compulsory for all amateur-radio stations to have operational equipment in the 40-meter band. This is to be able to participate at any moment in case of emergency. In this context, it also is mandatory for all clubs and amateur-radio organizations to maintain a schedule of radio watch and frequency control on all bands, under supervision of government authorities.

To get a license you must be Peruvian, either by birth or nationalization. If you are under 18 years old, you must get legal permission. Foreigners also can get licenses if their residence in the country is for more than 5 years, or 3 years if married to a Peruvian citizen or have Peruvian children.

The first license is issued for the Novice class after an examination on elementary electronics and communications and practical station operation. You must remain in that class until you get 100 QSL cards. To upgrade to the next category, you must apply for another examination on radio communications: You must be proficient in radio station operation and must be able to receive and transmit CW at 5 wpm.

You also must remain in that category until you receive another 100 QSL cards. Then you may apply for another examination on advanced electricity and electronic fundamentals, proficiency in radio station operation, and must be able to transmit and receive CW at 10 wpm.

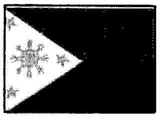
The Novice license is issued for a period of 3 years, not renewable. Thus, you must attend an examination within the next three years for upgrade or your license is cancelled. The other two categories also are issued for periods of three years but are renewable for similar periods. Licenses under a reciprocity agreement are valid for up to 90 days only.

The Direccion de Telecomunicaciones can authorize the installation and operation of amateur-radio stations to the military, radio clubs, and amateur-radio institutions, Peruvian Red Cross, Civil Defense, and scientific institutions in the areas of seismology, meteorology, and geophysics, to be operated *only* by licensed radio amateurs.

Of all the above, it is relevant to note that foreign operators can apply for a reciprocity-agreement license for only 90 days, but if he is a resident, he will get OA prefixes without restriction. Unfortunately not all countries have this prerogative. Also interesting is that amateur-radio stations installed at institutions like Civil Defense or Red Cross must be operated by licensed radio amateurs. In some countries, there are even citizens-band organizations or Civil Defense stations with amateur-radio stations operated by anybody able to press the PTT button.

The above information is based on current regulations, Decreto Supremo 009-74-TC, dated April 31, 1974.

That's all. I hope some fellow Peruvian will continue this writing from here on. In doing so, we'll see again the red and white flag waving in "*73* International."



PHILIPPINES

Leo M. Almazan WA6LOS/DU2
10098 Knight Drive
San Diego CA 92126

In my last column I wrote about the amateur-radio scene in the Philippines today. After a rather nice lengthy QSO with a W7 ham from Seattle, Washington, who happened to be in the Philippines before World War II, he not only told me how they used to DX on 40 meters with RCA's CW rigs, and Arc-88 receivers coupled to high zepp antennas, he also sparked my curiosity about the history of amateur radio in the Philippines.

After talking to the local OT hams in the country, I came up with pieces of information that any wireless nostalgia buff may find rather interesting. In this column I will talk about the history of amateur radio from World War I right up to World War II. In a subsequent column I will deal with the history from World War II right up to the early sixties.

The first wireless station in the Philippines was the powerful US Army spark station on Corregidor Island (made famous by General Douglas MacArthur's last-stand battleground) which was used to guide ships in and out of Manila Bay. The second famous station was the NPO, a US Navy spark station near their Sangley Point Naval Base. Both of these were built about or just before the US had entered World War I.

From this time till late 1919, the amateurs here followed US regulations since the Philippines was a US territory, and transmissions were considered illegal. Not till 1920 (even when the Philippines Legislature did not pass any radio laws till 1924) was anyone given permission by the Bureau of Post to start transmission. Even then, due largely to confusion, amateurs were still using their initials as callsigns. Before the 1920s, the local hams and US service personnel were on the air using whatever parts they could scrounge. Some were using old Ford spark coils, coherers, and galena detectors that were bought stateside from H. Gernsback's E. I. Co. catalog, then considered as the "bible of wireless."

In the early twenties, American hardware stores were *selling "wireless toys"* made by the famous A. C. Gilbert Co. of New York, the maker of the also-famous Erector sets. Each set consisted of an untuned crystal detector, headphones, an indoor aerial kit, ground connector, a key, and a single-circuit heavy-duty buzzer for the transmitter instead of the two-circuit, spark coil. With such sets, neighboring amateurs could play wireless and learn the code by actual communication. No license was required.

In the thirties, several ham stations sprouted in the country. The most notable was KA1HR, a multi-op, 1-kW station at a US Army base in Fort MacKinley. (The "KA" prefix was used since the country was still a US territory.) In the early thirties, the 1-V-2 "superwasp" was considered the standard station receiver. Other home-brewed receivers were built using the type-30 battery tubes. Commercial receivers also were available, like the National SW-2, SW-5, and the HROs.

Most Americans were already using multi-stage, crystal-controlled transmitters as required by US regulations, but the locals were still using self-excited, single-stage rigs.

Antennas were mostly half-wave sky wires, like the voltage-fed zepps with tuned feeders. Some used current-fed Hertz, or the single untuned, off-center-fed Windom antenna.

AM phone started appearing in the mid-thirties, exclusively operated by American hams mostly on 40 and 20 meters, though some were experimenting on 160 meters. Most transmitters were home-brewed and the receivers used were high-quality superhets to ensure stateside reception and to avoid QRM.

DXing remained on 40 meters even though competition from SW broadcasters was appearing in the band. The 40-meter CW bandwidth had been cut from 300 to 150 kHz during the International Radio Conference in Cairo in 1938, but CW DXing was still done primarily in this band. The US west coast came around 10:00 pm, South Africa around midnight, followed by the Europeans in the early morning. The top DX certificate then was the WAC, and many CW DXers had won it during the thirties.

Well this is it for now. Also, words are circulating that the Class B licensees will be sporting a "DW" prefix, so watch out for this new one.

POLAND

Jerzy Szymczak
78-200 Bialogard
Buczka 2/3
Poland

The Board of the SP DX Club issued 18 member diplomas recently. The last diploma number is 323. Every candidate for the diploma must produce QSL cards confirming mutual radio contacts with his own radio station with 75 countries on 6 continents. After a 6-month period, he can receive the diploma if he produces QSLs from 101 countries. Actually, 25 candidates are waiting for the diplomas.

There are 1710 honorary members of SP DX Club. To every European sender who establishes mutual communication with 15 full members, and to every extra-European ham who possesses at least 10 such QSLs, this honor can be done.

The SP DX Club celebrates its 25th anniversary in June this year. Eight SP senders have over 300 confirmed countries. There are 112 SP symbols on SP DX honor list for establishing 200 confirmed radio contacts. Leading radio amateurs of the SP DX Marathon are: SP3DOI (4334 points), SP3AGE (4235 points), SP7HT (4086 points), and SP5EWY (4054 points).

The first Polish winner of the WAC Satellite diploma suggests that Polish senders publish the 10 most-interesting QSOs of every year. On his own first list, he put, among others: the first QSO (April 3, 1983, on 7 MHz CW with SP9EVP, after martial law break), the *first* Polish contact via OSCAR 10 (August 15, 1983, with DJ2RE), and the first contact with Australasia via satellite.

Twenty Polish amateur stations took part in the All Asian DX Contest SSB 1983. The best were SP8EMO on 3.5 MHz, SP9EMI on 7 MHz, SP5LM on 14 MHz, SP7AWA on 21 MHz, SP6DNS on 28 MHz, and SP9ALM on SOMB and SP7KTE on MOMB. Diplomas are awarded these stations.

Polish Scouts radio amateurs are always on the go. On the occasion of the 70th anniversary of Scouting, the Scouts Communication Club organized the Leszno Contest UHF '84 that took place in December, 1983. Sixty UHF radio stations took part in the contest. The best individual stations were: SP6GZZ (2712 points), SP3JBI (1917 points), and SP9MM (1817 points). The best club stations: SP6WCY (1066 points), SP2KFE (169 points), and SP3ZHW (115 points). UHF radio amateurs from Leszno were informed that every Friday (2200 local time) has been set up as an activity day of Leszno stations using radiotelephones. Most of them work on 145.200 MHz with antennas with both vertical and horizontal polarization.

A new Scouts diploma, CZUWAJ, has been established recently. It is awarded by the Wroclaw team, SP6ZDA. To get this diploma one must acquire 50 points and assemble all the letters belonging to the word CZUWAJ (WATCH!). Selected stations send individual letters. Stations with stationary QTHs grant 4 points, and with local QTHs 6 points for every QSO. Eight points are awarded for QSLs with Scouts ceremonial stations. Contacts on UHF are counted double points.

In February this year, the first Polish repeater UHF-FM was set in motion. It has omnidirectional antennas with vertical polarization. The repeater works on the R channel. It receives signals on 145.000 MHz and transmits on 145.600 MHz. A 100-km range for the repeater has been estimated. Its callsign is SR9E.

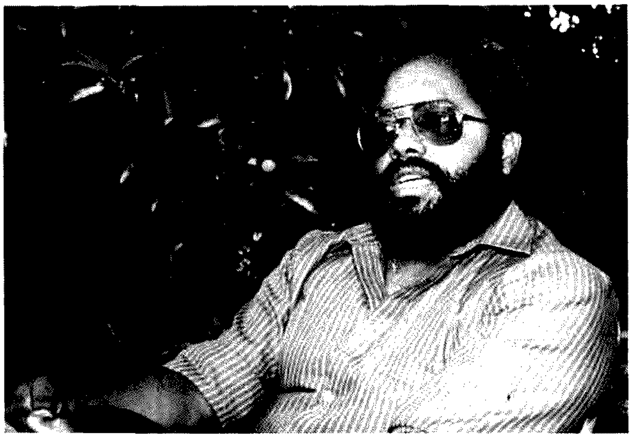
9Y4RD COMES HOME

On March 24, 1984, Roger de Weever 9Y4RD returned home for a well-deserved three-week vacation. Many of the DXers out there will be familiar with Roger's callsign, which has popped up in the past two years from such good DX locations as SU and STØ, and they may have received his attractive and amusing QSL.

At the monthly general meeting of the TTARS held on April 2nd, Roger was our guest of honor and addressed us for about one hour on his experiences in the Middle East. I was also privileged to have a lengthy (six-hour!) and very interesting eyeball with him about one week later.

Roger, now 35 years old and married to a very attractive lady, Carmen, began his career in commercial radio in 1969 as a ship's radio officer, after graduating from college in England. In 1970, he changed jobs to become a radio technician with TEXTEL (Trinidad and Tobago External Telecommunications). In the ten years that followed, he worked his way up through the company to the position of Acting Maintenance Engineer at the Satellite Earth Station located at Matura, in the northeastern part of the island.



Roger de Weever 9Y4RD.

1979 was the year that Roger made the decision to become a ham. On the strength of his experience both as a ship's radio officer and his technical experience as a communications engineer, he applied for the license and was issued the callsign 9Y4RD—his initials. (Here in Trinidad we are allowed to choose our callsigns, provided it has not previously been issued or otherwise reserved.)

Roger, in 1980, took up a job with the United Nations as a Field Service Officer in communications, to serve in the Middle East, and was based in Jerusalem, Israel. However, in the year prior to his departure, Roger, although only involved in limited activity on the air—mainly local 2m and some 10m DX—devoted considerable time to the training program of the TTARS and helped prepare about 30 students for the annual City and Guilds RAE Exam. Most of the students were successful in the examination, and needless to say, after Roger's departure, he was sorely missed by the TTARS.

In his new UN job Roger found the challenge he had been seeking! He has had to visit and work in such countries as Egypt, South Sudan, and Lebanon and is based in Israel—the world's hot spots! He has been involved in recommendations, design, and establishment of a variety of communications systems, both HF and VHF, in these countries, to assist both the local governments and the UN in their law-enforcement and peace-keeping activities. He is not involved in military communications and says that in spite of being based in one of the world's most turbulent areas, he has always been well treated and shown great respect and never felt that his life was in danger.

Roger's amateur-radio activity from the Middle East began in September, 1982, from Jerusalem, with a /4X callsign. His operation from SU commenced in October, 1982, and when in 1983 he was stationed in STØ for about 7 months, once again his ham equipment was lugged along. The equipment that Roger has used in his activity consists simply of a Yaesu 902 DM and a four-band trap dipole.

One of his ambitions from each of the QTHs he has operated has been to get a DXCC, and he has so far achieved this from: STØ—about 2500 QSOs and 130 countries; SU—9000 QSOs and 185 countries, and 4X—1500 QSOs and 150 countries. Whereas Roger enjoys ham-radio operation from comparatively rare DX locations and will always try to comply with another ham's request for skeds, etc., he detests his operations being referred to as DXpeditions. He does not go on DXpeditions in the Middle East. He is simply working in whatever country he is QRV from, and all his amateur-radio activities are done in his spare time as a form of relaxation.

Incidentally, Roger has been doing quite a bit of badly needed PR work for ham radio in countries such as SU and STØ, where amateur radio is neither understood nor encouraged as a worthwhile hobby. In his job he works alongside many locals, most of them being qualified radio technicians, and wherever possible he tries to educate these persons and any others interested in the benefits and usefulness of this hobby we all enjoy.

One interesting fact revealed during the course of our discussion was the way in which ham-radio activity has assisted Roger in his job. The practical experience gained in antenna performance and construction, propagation conditions both on HF and VHF, and even just the way hams get things done when others fail, have all combined to make him successful in his job. It is especially for this reason that he has always made a point of lugging along his trusty 902 DM, as heavy as it is, wherever he has traveled.

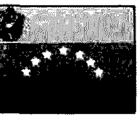
By the time this article appears in print, he will long since have returned to continue his tour of duty in the Middle East. Roger's plans in the coming months include stints in SU and STØ. He already has re-equipped himself with new radio gear. From his home QTH he will be using the new FT-980 by Yaesu and a Cushcraft R3 triband vertical—the one that's ideal for apartment dwellers as it needs no radials! His portable operations will be made with a much more compact and lightweight transceiver, the Icom IC-730, and his old 4-band trap dipole.

Roger has indicated that the following are some of his favorite operating frequencies and times:

14.220 MHz	0700Z
21.157 MHz (DK9KE Net, mainly weekends)	1000Z
21.335 MHz	1800Z
28.550 MHz	1300Z
14.332 MHz (YL system)	Occasionally

All QSLs for 9Y4RD/... should be sent directly to his QSL Manager, KA2DDJ, as he does not have the time nor QSL cards to handle QSLs himself.

Wherever Roger is QRV, you should have no difficulty identifying him, since, as a patriotic Trinidadian, he plans always to retain his 9Y4RD callsign and operate as a portable.



VENEZUELA

Luis E. Suarez OA4KO/YV5
Apartado 66994
Caracas 1061-A
Venezuela

CIRCUITO 2 (YV2)

In Venezuela, call area 2 is composed of the states of Tachira, Merida, and Barinas. The first two are Andean, with cities at altitudes ranging from 100 to 3100 meters. Barinas state, however, is located in the plains on the eastern side of those states and faces the Andes.

San Cristobal is the capital city of Tachira. It is located in a hilly terrain, almost like that of San Francisco. It is a modern city with all the traffic and noise that civilization carries on.

Down the Andes there is another city with a funny name: La Fria (the Cold). When you arrive in that city you will experience tropical heat, but La Fria earned its name from a type of malaria which caused terrible chills and continuous chattering of the teeth. At first it was just some black humor, but the name remained. Today it is a prosperous zone with a superhighway linking this city and San Cristobal. San Cristobal's nearest airport is at La Fria.

Merida, the highest state in the Andes is called the Techo de Venezuela (Roof of Venezuela). Captain Juan Rodriguez Suarez (no relation) founded it in 1558. In fact, he was not authorized to found cities, so he was rushed to Bogota, arrested, judged guilty of the usurpation of Royal prerogatives, and sentenced to be dragged by the tail of his horse until dead and then to be quartered. However, he escaped to Venezuela and got asylum.

In Merida is located the highest mountain of Venezuela: Pico Bolivar. This mountain is 5,700 meters high and wears a perpetual snow dress. It has the highest and the longest cable car in the world; it takes one hour if you go straight to the top. There is some skiing here, but it is not recommended unless you are professional. "It is out of this world, and astronaut training is recommended for the successful Pico Espejo skier" (*Ve Venezuela*).

Driving from Merida city down the plains, and heading to Barinas, is something you'll never forget in your life. At first you go up the mountains to the Andean paramo. It is as inhospitable, cold, cloudy, and damp in the rainy season as it is dry and drab in the dry season. It is so isolated that you feel you are between life and death. You feel the necessity to stop your car and listen to the silence. I did and was surprised to know that the only plants in the zone, the frailejones, are really fragrant and they perfume the paramo.

At Apartaderos, midway between Merida and Barinas, you may visit CIDA, an astrophysical institute, with its four telescopes, among which are Coude Cassegrain, a double astrograph and a great reflector, as well as a Schmidt Camera. Visitors are welcomed.

Continuing to Barinas, you may have direct radio contact now via 2m FM repeaters with Caracas or Maracaibo, as I explained in a past column. Continuing with the trip and heading to Santo Domingo, you see the vegetation begin to change. After Santo Domingo, a snaking road heads you down to the plain. The mountains become green and you see small wa-

terfalls coming near the road. Temperature increases and tropical vegetation breaks all around as you approach Barinas, the capital city of Barinas state.

Barinas is flat and becomes inundated during the rainy season. Since the northwest part of this state is toward the Andes, most of the towns are located in the rolling foothills at the edge of the mountains.

In my next column, I will begin describing call area 3: Lara, Yaracuy, and Portuguesa.

MAP EXCHANGE

I like city maps; if anybody out there is interested in maps, too, let me know. Send me a map of your city and I will enchange with the map of Caracas. Please be sure it is a detailed map with all streets. (Cannot use those which advertise relative locations of historical or interesting places, like tour maps or souvenir maps.) From the USA, Rand McNally is preferred; Dolph is OK. If you know your Maidenhead grid locator (with 6-character precision), please mark your QTH. Otherwise please don't. Let me find it myself!

COMUNICA BULLETIN

Also I wish to mention that I'm publishing a Spanish newsletter named *COMUNICA.* If there is anybody wishing to spread any information to Venezuelan and Latin American radio amateurs, let me know. The bulletin is distributed monthly in all Latin American countries. Subscription is US$15.00 first-class Air Mail per twelve issues. As far as I know this is the first communications bulletin in Spanish ever published and distributed in 19 countries.

If you would like to take a look, send me your address and I will forward you a sample. Maybe you would like to include, with your request, news from your radio club for publication. If somebody is publishing something similar, an exchange is desired. Polish, Chinese, and Swahili bulletins are accepted.

FEEDBACK

I wish to thank all those colleagues who sent cards and letters. All those that requested information and services were replied to or the request accomplished. I have published in *COMUNICA* the requests I couldn't answer in the hope that somebody was able to reply directly.

Regarding the article on parabolic antennas (*73,* May, 1984), I wish to mention that the article was intended to be as tutorial as possible. Really, I have no plans or drawings for construction and the intention was that you personally develop your own design. If you don't have the ability to construct a parabola, neither a drawing or a picture will help.

I guess the best solution is to make the drawing yourself and find somebody who feels comfortable with mechanical structures to help you in construction. Another approach is to get an already-made parabola and to experiment with different feeders. With the information in the article you would be able to know what you get and what you need for your particular application. The last recommendation is that you start with a 1-meter dish and then go ahead with a larger one if necessary.

FUN!

John Edwards KI2U
PO Box 73
Middle Village NY 11379

CALLSIGNS

What does your callsign mean to you? I know my call means a lot to me. On the air, it's my name. When I visit hamfests, my callsign badge lets people know who I am. There may be hundreds of thousands of John Edwardses on this sad old planet, but only one KI2U. Thank heaven.

Unlike my name, I've held a number of calls over the years, including WB2IBE (my original), WR2APG, WA2DCS, and of course KI2U. When I upgraded from Advanced to Extra back in 1980, I had to do some serious soul searching before changing my call. My old ID had served me well over the years and, naturally, I was reluctant to make such a drastic change in my amateur-radio lifestyle. Still, a snappy 2 × 1 call has its advantages in pileups, so I reluctantly turned in my old 2 × 3 trademark for KI2U.

ELEMENT 1
MULTIPLE CHOICE

1) Before the FCC reshuffled the amateur callsign allocation process in 1978, what did a WT prefix signify?
   1) A Technician-class licensee
   2) A temporary license
   3) Nothing in particular
   4) A ham in the third radio district
2) WN prefixes were formerly reserved for:
   1) Novices
   2) Interim licensees
   3) Secondary licenses
   4) Repeaters
3) Tuning around 20 meters one night, you hear a station signing KA0QRM. Why do you suspect he is a bootlegger?
   1) The FCC doesn't usually issue call suffixes that are also Q-signals
   2) KA calls aren't allowed on 20 meters
   3) The FCC doesn't issue calls with a Qxx suffix
   4) You don't know
4) What's wrong with WR2APG, New York's favorite 220-MHz slow-scan TV repeater?
   1) It's using an expired call
   2) Repeaters aren't allowed on 220 MHz
   3) Slow-scan TV isn't allowed on repeaters
   4) Nothing
5) What was the callsign of the ARRL's first headquarters station?
   1) W1AW
   2) 1AW
   3) W1ARRL
   4) W1MK

ELEMENT 2
FILL IN THE BLANKS

Fill in the calls of these prominent hams of the past and present:

1) Arthur Godfrey _______
2) King Hussein _______
3) Barry Goldwater _______
4) Mahmud Reza Pahlavi _______ (Shah of Iran's son; now the current Shah)
5) Tom Christian _______

ELEMENT 3
TRUE-FALSE

	True	False
1) The FCC programs its computer so it won't issue obscene or suggestive amateur callsigns.	_____	_____
2) All broadcast stations east of the Mississippi have W callsigns.	_____	_____
3) WHAS is located in Louisville, Kentucky.	_____	_____
4) A broadcast station may select its callsign.	_____	_____
5) OSCAR 8's callsign was W12OSC.	_____	_____
6) Lee DeForest, famed radio inventor, held amateur call 1DF.	_____	_____
7) The FCC issued the first K calls to continental US hams during 1948.	_____	_____
8) W2XAM is *not* a ham callsign.	_____	_____
9) The Federal Radio Commission began issuing W and K calls in 1948.	_____	_____
10) KCBS is located in Los Angeles CA.	_____	_____
11) Hiram Percy Maxim's first callsign was SNW.	_____	_____
12) Marconi once received an FCC citation for failing to properly identify his station.	_____	_____

ELEMENT 4
MATCHING

Match the prefixes in Column A with the countries in Column B.

Column A	Column B
1) CP	A) Grenada
2) LU	B) Sikkim
3) 5H1	C) Philippines
4) LZ	D) Malawi
5) J3A	E) Colombia
6) GU	F) Iran
7) 8R	G) Zanzibar
8) DU	H) Switzerland
9) 3D2	I) Mauritania
10) 5T5	J) Papua New Guinea
11) AC3	K) Ireland
12) VR6	L) Soviet Union
13) HK	M) Sudan
14) M1	N) Bolivia
15) EP	O) Turkey
16) D4C	P) Fiji Islands
17) EI	Q) Guyana
18) CE	R) Bulgaria
19) 7Q7	S) Cape Verde
20) 9V1	T) Singapore
21) 5U7	U) Argentina
22) P29	V) San Marino
23) TA	W) Chile
24) HB	X) Guernsey
25) ST	Y) Pitcairn Island
	Z) Niger

THE ANSWERS

Element 1:

1—2 Usually issued by the local field office when Gettysburg screwed up an application.
2—1 Also KN prefixes for a while.
3—1 Sort of helps to prevent confusion.
4—1 All WR prefix repeater calls have expired.
5—4 It got wiped out in a 1936 flood.

Element 2:

1—K4LIB
2—JY1
3—K7UGA
4—ex-EP1MP
5—VR6TC

Element 3:

1—True All the funny ones.
2—False Most, but not all (e.g., KDKA in Pittsburgh).
3—True All 50 kW of it.
4—True But hams can't. Not fair, really.
5—False Satellites don't require a call.
6—False DeForest wasn't a ham.
7—True During the fall.
8—True It's a call for experimental stations.
9—False The year was 1929.
10—False It's in San Francisco.
11—True Around 1911, the days when you could make up your own call.
12—False Marconi's radio experiments were completed by the time the FCC came into being.

Element 4:

1—N, 2—U, 3—G, 4—R, 5—A, 6—X, 7—Q, 8—C, 9—P, 10—I, 11—B, 12—Y, 13—E, 14—V, 15—F, 16—S, 17—K, 18—W, 19—D, 20—T, 21—Z, 22—J, 23—O, 24—H, 25—M.

SCORING

Element 1:
Five points for each correct answer.
Element 2:
Five points for each call correctly filled in.
Element 3:
Two points for each correct answer.
Element 4:
One point for each correct match.

How did you do?
1-20 points—Called out
21-40 points—Call for help
41-60 points—Call back
61-80 points—On call
81-99 points—A call to remember!

DEALER DIRECTORY

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego, 827-5732 (Reno NV).

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.

San Jose CA

Bay area's newest amateur radio store. New & used amateur radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. Shaver Radio, Inc., 1775A S. Winchester Blvd., Campbell CA 95008, 370-6665.

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Kenwood, AEA, Kantronics, Santec. Full line of accessories. No sales tax in Delaware. One mile off 1-95. Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.

Boise ID

Rocky Mountain area's newest ham dealer. Call RJM first for AEA, Azden, KDK, Ten-Tec, Butternut, Cushcraft, and more! RJM Electronics, 4204 Overland, Boise ID 83705, 343-4018.

Preston ID

Ross WB7BYZ has the largest stock of amateur gear in the Intermountain West and the best prices. Call me for all your ham needs. Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.

Littleton MA

The reliable ham store serving NE. Full line of ICOM & Kenwood. Yaesu HTs, Drake, Daiwa, B&W accessories. Curtis & Trac keyers. Larsen, Hustler, Telex/Hy-Gain products. Mirage amps., Astron P.S., Alpha Delta protectors, ARRL & Kantronics instruction aids. Whistler radar detectors. Full line of coax fittings. TEL—COM Electronic Communications, 675 Great Rd. (Rt. 119), Littleton MA 01460, 486-3400/3040.

Livonia MI

Complete photovoltaic systems. Amateur radio, repeater, satellite, and computer applications! Call Paul WD8AHO. Encon Photovoltaics, 27600 Schoolcraft Road, Livonia MI 48150, 523-1850.

Lincoln NE

G&C Communications is a full-line distributor of major-line amateur equipment and accessories, antennas, and everything. 4230 Progressive Ave., Lincoln NE 68504, 46-RADIO.

Derry NH

Serving the ham community with new and used equipment. We stock and service most major lines: AEA, Astron, Azden, B&W, Cushcraft, Hy-Gain, Hustler, ICOM, Kenwood, KLM, Larsen, Mirage, Mosley; books, rotors, cable and connectors. Business hours 9-7 Monday through Thursday, and 9-5 Friday and Saturday. Rivendell, 68 Warner Hill Road, Derry NH 03038; 434-5371.

Albany, New York UPSTATE NEW YORK

Kenwood, ICOM, Ten-Tec, Belden, Cushcraft, Larsen, Hustler, ARRL, Hy-Gain, B&W, MFJ, Mirage. New and used equipment. Serving the amateur community since 1942. Adirondack Electronics, Inc., 1991 Central Avenue, Albany NY 12205, 456-0203 (one mile west of Northway exit 2W).

Columbus OH

The biggest and best ham store in the Midwest featuring Kenwood and other quality products with working displays. We sell only the best. Authorized Kenwood service. Universal Amateur Radio, Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.

Dallas TX

IBM PC/XT kits, supplies, expansion products; video restorer kits for pay TV, CATV, satellite hobbyists' electronic project kits/appnotes. More than 9000 parts in stock: semiconductors, ICs, discretes, video accessories, tools, audio, automotive, cabinets, computer peripherals. Please write for your free 60-page catalog: Sabet Electronics, 13650 Floyd Rd., Ste. 104, Dallas TX 75243; 783-4950 (formerly I.E.).

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the December '84 issue must be in our hands by October 1st. Mail to 73 Magazine, Peterborough NH 03458. ATTN: Nancy Ciampa.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

OUR WORST ENEMY

It was back around 1976, shortly after the Carter revamping of the Commissioners, when we hams had our first serious problem with the FCC. In case you are new to amateur radio or are short of memory, here's what happened.

The first problem facing the new Commission had to do with a proposal to eliminate ten-meter linears. This was in response to enormous interference problems from cheap and dirty linears made for CB use on 11 meters, which were proliferating. CB was in its heyday and television sets everywhere were driving their owners crazy as CBers drove by or worked DX from their home locations with their kilowatts.

The FCC had no way of knowing that in a few months their actions would solve the problems in an unexpected way when they expanded the service to 40 channels, almost killing CB entirely.

The situation was severely aggravated when the previous Commission outlawed 11-meter linear amplifiers. This forced the legitimate manufacturers out of business and left it open to underground manufacturers. Clean-emission standards were henceforth ignored and "ham 10-meter" amplifiers flooded in from truckstops and from under CB-dealers' shelves.

The new Carter FCC held a hearing on whether to outlaw 10-meter linears entirely. The main speaker was the ARRL legal counsel, who proceeded to lecture them like school kids. I watched in mounting horror as Booth went on endlessly while the Commissioners fumed and then walked out on him. That day we lost not only that rulemaking, but all sympathy from the FCC for four years. We were fortunate that they did not follow up on their plan to make a new personal-radio service with CB and ham radio combined.

A Fresh Start

The Reagan FCC gave us a new change in 1981. I went down to Washington and talked with each of the Commissioners personally, giving them some background on the past, present, and potential future of amateur radio. They were eager to help our service get back into a strong growth mode so it could again attract teenagers and thus bring the country desperately needed engineers and technicians—as it had done so well before the ARRL's incentive-licensing disaster of 1963.

Since no-code had been the breakthrough for growth in Japan, they were eager to try it out

PUBLISHED REPORTS that *73* had been put up for sale by its parent company, CW Communications, Inc., were absolutely true. CWCI felt that *73*, as an amateur-radio magazine, did not fit in with its 50 or so other computer publications. Pro-*73* forces, however, suggested that modern ham techniques, such as packet radio, are indeed high tech and also that selling a successful property might not be a sound idea. CWCI subsequently *withdrew* its offer to sell and committed its *full backing and support* to *73*. As a result, we believe our readers and advertisers will be seeing some exciting improvements in *73* as we enter our 25th-anniversary year!

SOFTWARE PIRATES are looking over their shoulders after Kantronics successfully prosecuted Cindy Gladwell of Cindy's Computer Software. Cindy sold a pirated copy of Kantronics' Hamtext computer program, along with a full set of documentation, to Mike Forsyth at the Michigan State ARRL Convention in Detroit. Mike happens to be Marketing Director of Kantronics. Ms. Gladwell was served an injunction to halt all software-reproduction activities and directed to forfeit $2000 in damages to Kantronics.

THE BID FOR 220 MHZ by several commercial interests has been stalled at press time. The petition by Sideband Technology, Inc., RM-4831, has been put on hold while the FCC investigates charges of conflict-of-interest filed by the Inland Waterway Communications System. Art Reis K9XI, editor of *220 Notes*, has asked for a congressional investigation into the activities of the FCC Office of Science and Technology, which seems to be behind the bid for 220.

THE MOUNT GREYLOCK REPEATER was saved from an untimely demise recently when Governor Dukakis of Massachusetts signed into law a bill giving the Northern Berkshire Amateur Radio Club a twenty-year lease on the repeater site. Overwhelming support from amateurs across the country in the form of cards and letters was instrumental in preserving this heavily-used machine.

A SPREAD-SPECTRUM BEACON is now on the air near Falls Church VA. According to Chuck Phillips N4EZV, the system operates from 144.5 to 147.7 MHz, with a hop rate of 10 per second. Output power is 25 Watts, and the beacon transmits a series of Vs after an identification that is simulcast on the AMRAD repeater, 147.21/.81. After normal business hours, the beacon may be turned on by sending the touchtone™ digits 4-3-2-1 on 144.5 MHz. Chuck has plans for HF spread-spectrum beacons on the 10- and 15-meter bands. If you are interested in the application of this fascinating technique to amateur radio, contact Chuck Phillips at Tactical Communications, Inc., 5711 B Center Lane, Falls Church VA 22041.

PACKET RADIO will be the subject of the next North American Teleconference Radio Net (TRN), heard through over 150 gateway stations across the United States. Two of packet radio's pioneers, Lyle Johnson WA7GXD and Harold Price NK6K, will be the featured speakers. Lyle is president of the Tucson Amateur Packet Radio Society (TAPR) and was the primary influence behind the development of the TAPR terminal-node-controller (TNC) hardware. Harold is a director of TAPR and worked on the software end of the TAPR TNC. For a complete list of TRN gateway stations, send an SASE to TRN Manager, c/o Midway Amateur Radio Club, PO Box 1231, Kearney NE 68847-1231, or check CompuServe's Hamnet XA4 database.

Massachusetts Governor Michael Dukakis chatted with nearly 125 hams after signing legislation saving the Mt. Greylock repeater. That's Warner W1YBT on the right.

SEVERAL ARRL QSL BUREAUS have new addresses.

VE6: CRRL Incoming Bureau, N. F. Waltho VE6VW, General Delivery, 9714 94th Street, Morinville, Alberta, Canada T0G 1P0.
SWL: Mike Witkoski, 4206 Nebel Street, Stevens Point WI 54481.

THE FAILURE RATE of the new volunteer-given amateur exams is exceptionally high. Most groups report that only 25% of their applicants are upgrading. There's a good deal of confusion regarding who is actually running things—although the *W5YI Report* and the ARRL are both Volunteer-Examiner Coordinators (VECs) for all 13 districts, many districts have up to *seven separate groups* acting as VECs. In some areas, the district VECs are bowing out in favor of the League, which is still trying to bully its way into control of the program. In any case, the FCC will be out of the testing business at the end of the year. For a complete list of VECs, send an SASE to *73*, Pine Street, Peterborough NH 03458, Attn: VEC LIST.

FCC HAS NAILED another jammer. Dave Meehan W7IVK has had his Advanced-class amateur license suspended for one year for willfully interfering with communications on the 40-meter band. After the year is up, Meehan will be permanently barred from operating in the 7235-to-7280-kHz segment of the band.

$140,000 WORTH OF ILLEGAL CB GEAR was seized by US Marshals recently in one of the nation's largest radio-related raids. Most of the equipment consisted of linear amplifiers and subassemblies destined for use in the CB service. The distributor, D&D, Inc., of Shelby NC, faces fines of up to $10,000 and prison sentences for its violation of the Communications Act of 1934.

CONGRATULATIONS TO ROY NEAL K6DUE on his new duties as Deputy Bureau Chief for News Operations for NBC. Roy had previously served as the science correspondent for the network, giving live on-the-air commentary during most of NASA's space shots. Good luck, Roy!

THIS MONTH'S NEWS was courtesy of the *W5YI Report*, *Westlink*, and WA1HXQ.

Color Computer SSTV: Part I

Turn your CoCo into a complete SSTV terminal! How? First, build this high-resolution display system.

Photo A. Multimode display board, showing the physical size of a production display interface. The board has 16K of display memory.

Clayton W. Abrams K6AEP

San Jose CA 95124

Dr. Ralph A. Taggart WB8DQT
602 Jefferson Street
Mason MI 48854

This two-part article describes a high-resolution display system for the Radio Shack Color Computer® (CoCo). This system provides the CoCo computer with more display capability than any low-cost computer. You might ask why you should use your CoCo to display and generate television images. One answer is, for communications.

Imagine taking your CoCo with a hardware-software interface and connecting it to amateur-radio equipment and transferring a picture to

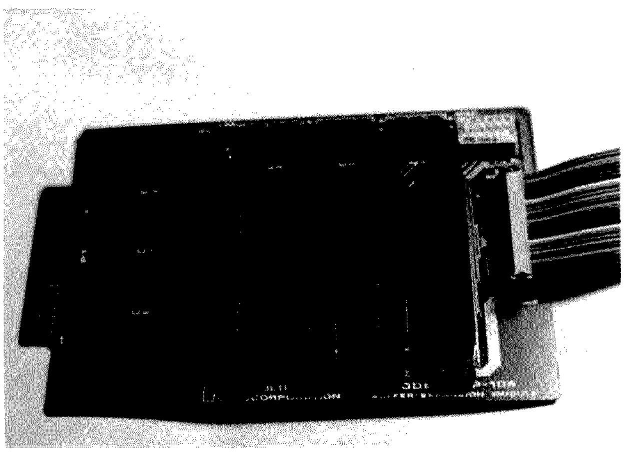

Photo B. Multimode CoCo interface board, which plugs into the expansion interface of the CoCo. A 26-pin flat cable interconnects the interface board and the display board.

someone miles away, or receiving weather-satellite pictures. The digital-television-display field is one which has not been explored by the amateur-computing community, and only a small amount of commercial equipment exists for such applications. In this article, instructions will be provided to construct a card to display high-resolution images and provide interfaces to receive weather-satellite pictures or amateur-radio SSTV.

Before plowing ahead with a lot of technical jargon and confusing terms, some definitions are in order.

Background

In display terminology two terms are particularly important. These terms are used also in television. The first is pixel, and it relates to the smallest element of a picture which can be seen on the TV screen. In normal TV, the pixels are so small that they tend to blend together to form a contiguous image. In digital TV, a pixel is a unit in the picture which can be seen by the unaided eye. Each pixel in digital TV has an intensity or discrete color. The main goal in digital TV is to place the most pixels on a line to form the smoothest image. To do this as well as standard TV does takes a lot of complex and costly circuitry.

The second term is number of lines per picture. In the USA, standard TV has 262 lines per frame or 525 lines per interlaced picture. In digital TV, the number of lines is often reduced from normal TV for cost and simplicity reasons.

If a digital-display system could be developed around a standard microprocessor system, the system would be very versatile. The few commercial display systems which have been developed to date have some disadvantages.

Expandability. Microprocessors have been installed in some of the new display-system designs. All of these units are not user-programmable. Most vendors would rather provide users with new units when their function is to be expanded. If a system were to be based on a commercial microprocessor with a good software base, the system could be expanded as technology progresses.

Fixed Architecture. Most commercial systems are built around a large planar board with lots of ICs and discrete components. These units are designed for a specific application and a limited life span. Adding interfaces like FAX and other applications is difficult. For this reason, the modular approach of functional units connected to a microprocessor makes good sense.

Up to a few years ago, digital TV was not possible. With the explosion of the semiconductor industry, the price of ICs has fallen to a level which makes this economically possible. Most of the early digital TV scan converters used were hardware-only devices. These units were very dumb and

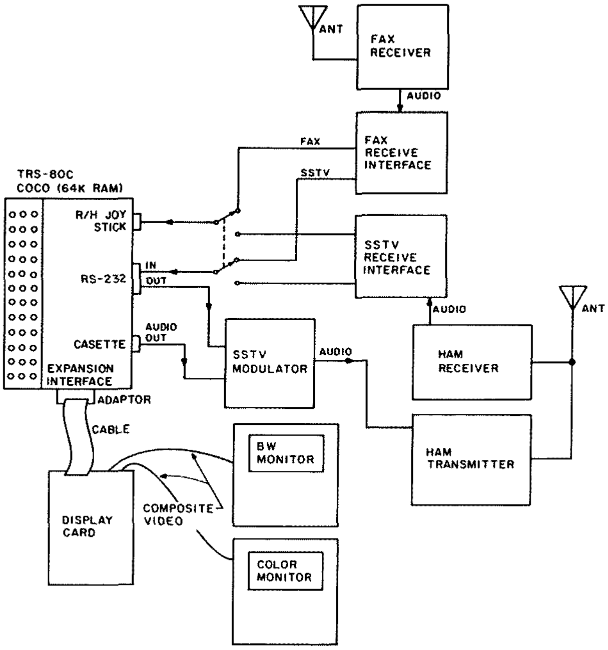

Fig. 1. System block diagram, showing the interconnection of the computer and all the interfaces.

could only generate and display images. The explosion of digital computers and the incorporation of digital displays in computers makes the whole concept very exciting. Once an image is placed in the computer, almost anything is possible: communications, image analysis by computer for manufacturing inspection, medical applications, or art forms for their own sake.

Two applications will be described in this article. The first application is amateur-radio slow-scan television; the second is weather-satellite reception. While the applications are similar in that they require some means of picture displaying and a

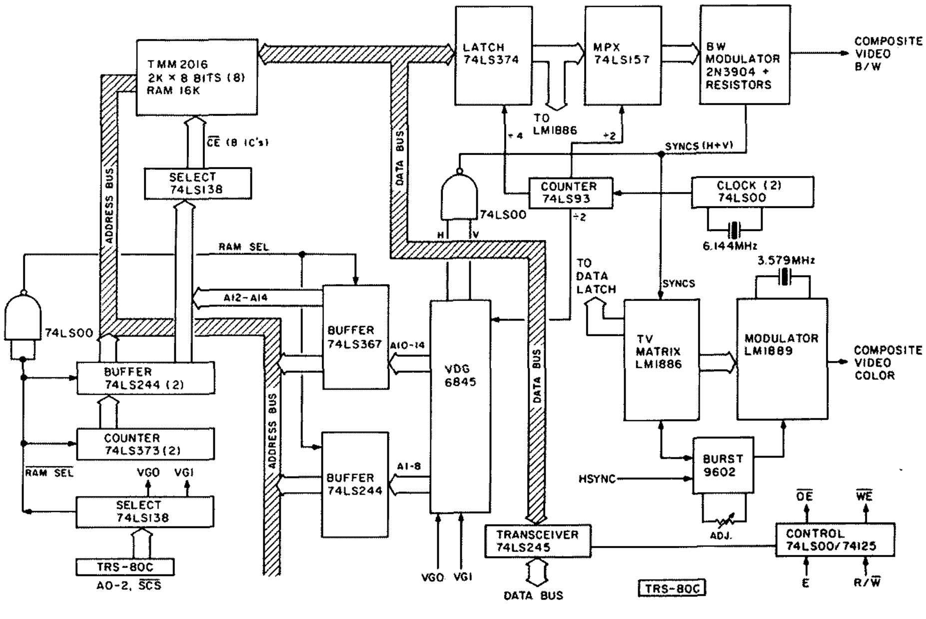

Fig. 2. Display block diagram, showing how the display interface functions. Only the important ICs are shown.

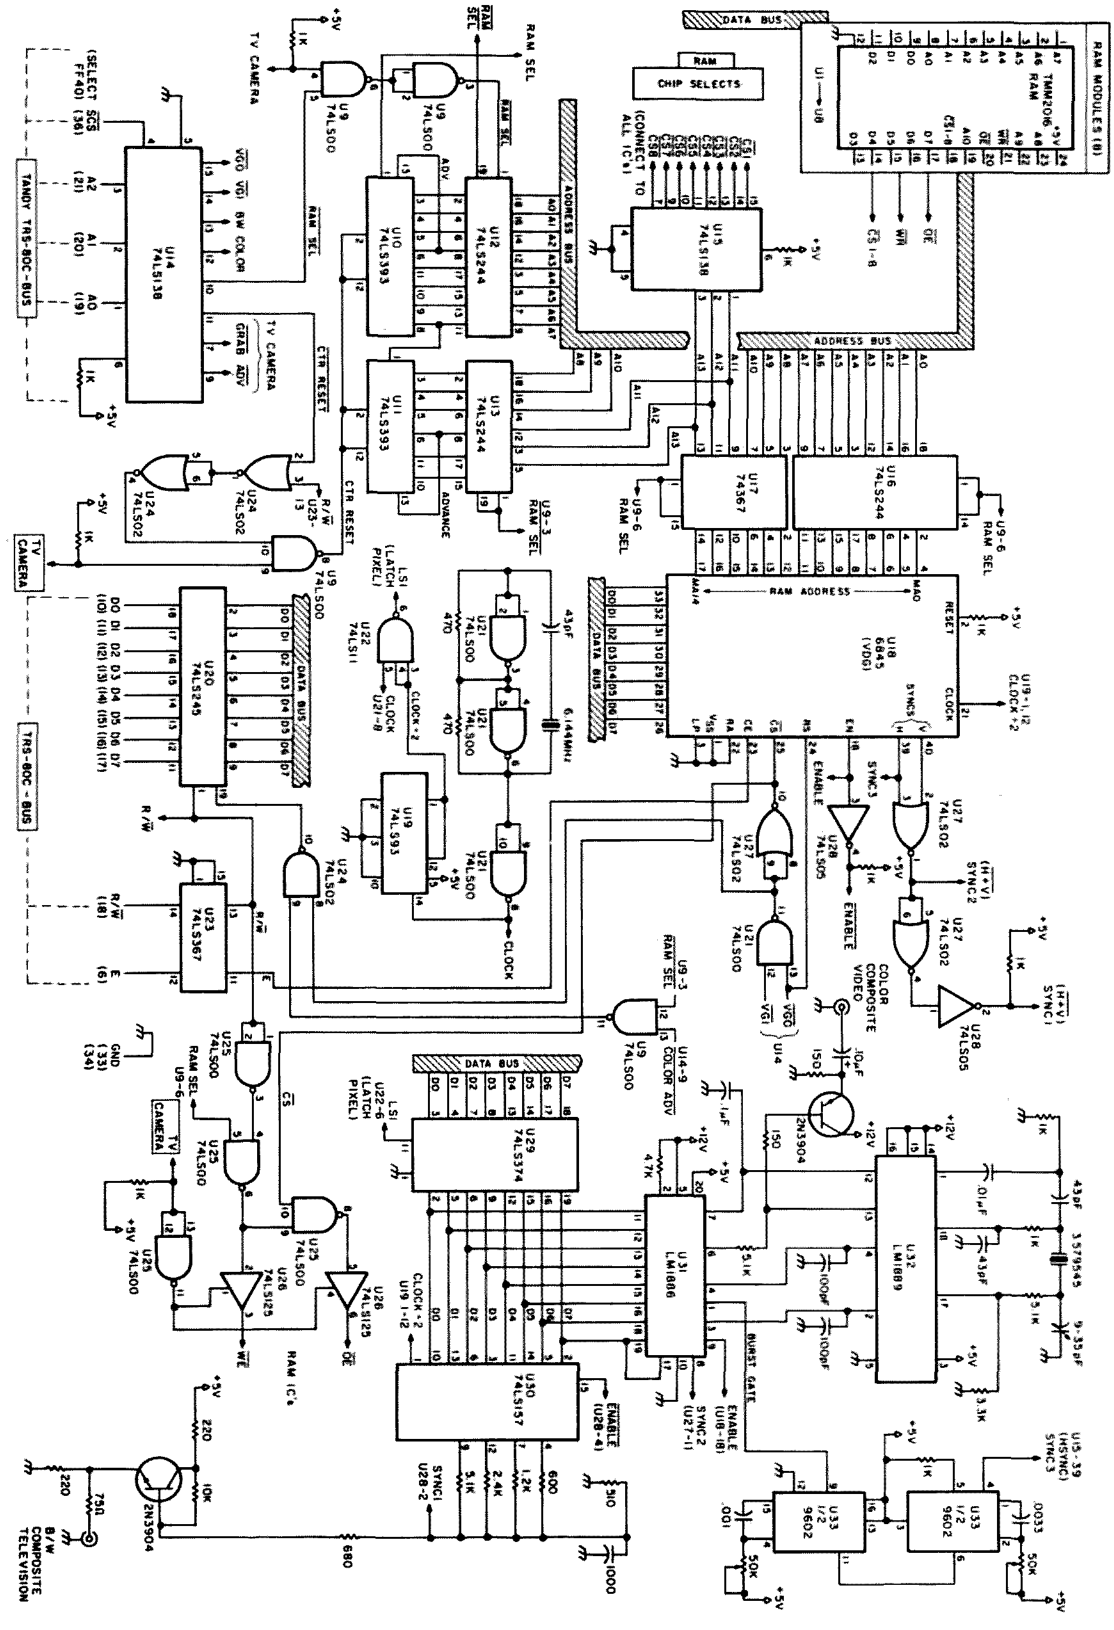

Fig. 3. Display board schematic.

hardware interface to properly condition the signal, and each requires trade-offs and compromises to achieve adequate results, we will treat them separately in order to do an adequate job on each.

SSTV

Since all interfaces use simple hardware, the heart of the system is software. It would be impossible to publish an entire software package in an article of this type. To date, thousands of lines

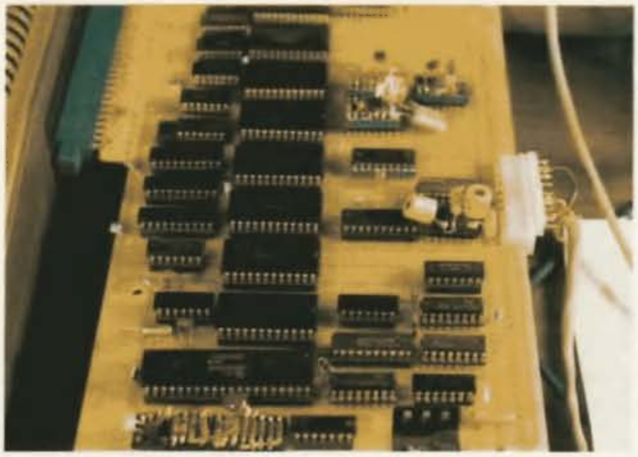

Photo C. The prototype board by K6AEP was one of the first display boards constructed. The board is plugged into a CoCo. The board was point-to-point wired and is exactly like the schematic in Fig. 3. All of these photos in part I of this article were generated by this board. The same results can be achieved by the commercial display boards.

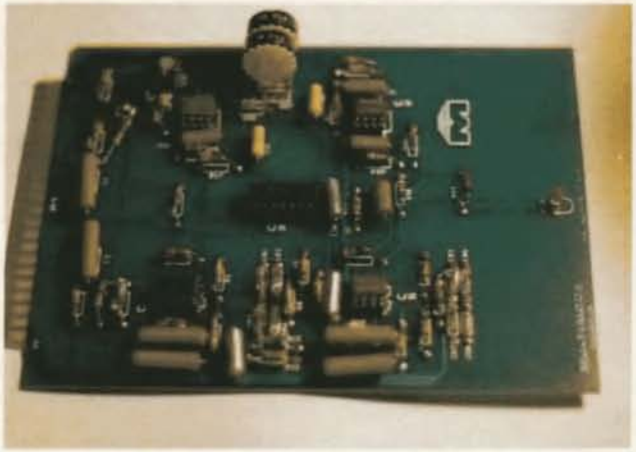

Photo D. A multimode SSTV receive interface. This board is a commercial version of the SSTV receive interface. The physical size is the same as the display board.

of code have been developed. What will be provided here is a technical description of how the software and hardware interfaces function and the steps necessary to develop code. You will find it possible to modify the concepts we present for interfacing with any microprocessor system.

The Display Criteria

Since the main goal of the display card is to produce quality images, it is important to make the picture density as high as possible. This requires the addition of RAM memory in which the image will be saved and displayed. Experimentation by many people over a period of years has determined that a minimum of 128 pixels per line is required for low-resolution images, with at least 16 gray levels. Some experimentation which I conducted in mid-1982 indicated that a minimum of 256 colors per pixel is required to display low-resolution color-TV images.

Armed with this information, a design criteria of 256 pixels per line, 16 gray levels, on 128 lines was defined for black and white displays. This equates to a display size of 16K of display RAM. With a little clever programming and slight reconfiguration of data bits, a total of 256 colors can be displayed for each pixel with 128 pixels per line on 128 lines.

Obviously, a system can be constructed with higher resolution, but as the digital-display density increases so do the cost and complexity. Since this project was created for the average hobbyist with a limited budget, the above criteria seem adequate for today's technolgy.

Hardware Design

It is unfortunate that no off-the-shelf module or design provides the necessary ingredient to display TV-type images. Many manufacturers have developed display-controller ICs for computer terminals, but in most cases they are unusable in TV applications. One of the few ICs which make the job easier is the Motorola 6845. This IC is the heart of the display board and causes the image to be displayed.

The card is designed to attach to the Radio Shack TRS-80C Color Computer, but the design concept is so basic that it can be altered to attach to any microcomputer. The card functions by first generating or placing an image in the main memory of the computer. The TV image can be received through a slow-scan demodulator attached to the receiving equipment then connected to the joystick input of the computer.

Another method of image generation is to attach a special hardware interface to the display card and frame-grab the image into the display card from a TV camera. At this time the TV-camera interface has not been developed. When using the TV camera, the image will be loaded into the video card first and then transferred by computer software to main memory.

System Description

Fig. 1 provides a block diagram of the entire system. The TRS-80C in this application acts as an intelligent controller. All interfaces are very primitive and cannot function without intensive control from the computer. When an image is to be displayed from the receiver, the audio tones are first detected by the display demodulator and converted to two types of signals: sync pulses and a dc voltage which changes as a function of the input audio frequency. These signals are connected to the CoCo's RS-232 input and the joystick input.

The joystick input is actually an analog-to-digital converter which can be used to digitize slow-scan TV video into picture information. All of the operation is controlled by software in the CoCo. When digitized, the pixels are transferred to the display card and immediately displayed. For transmission, the image is first created by software and placed in the CoCo's memory. To transfer the image to a transmitter, the sync pulses are controlled by the RS-232 output line and the video is controlled by the computer's cassette output, which is a digital-to-analog converter.

The above process is true only for black and white television. Color digital TV is more complex. Color TV is developed or transferred from three image planes. Each plane consists of the three prime colors (red, green, and blue). When the three frames are mixed together, a color image is formed. The image can then be transferred to the display card. The transmission method of colored television is either by frame-sequential or by a colored line-sequential multiplexed method.

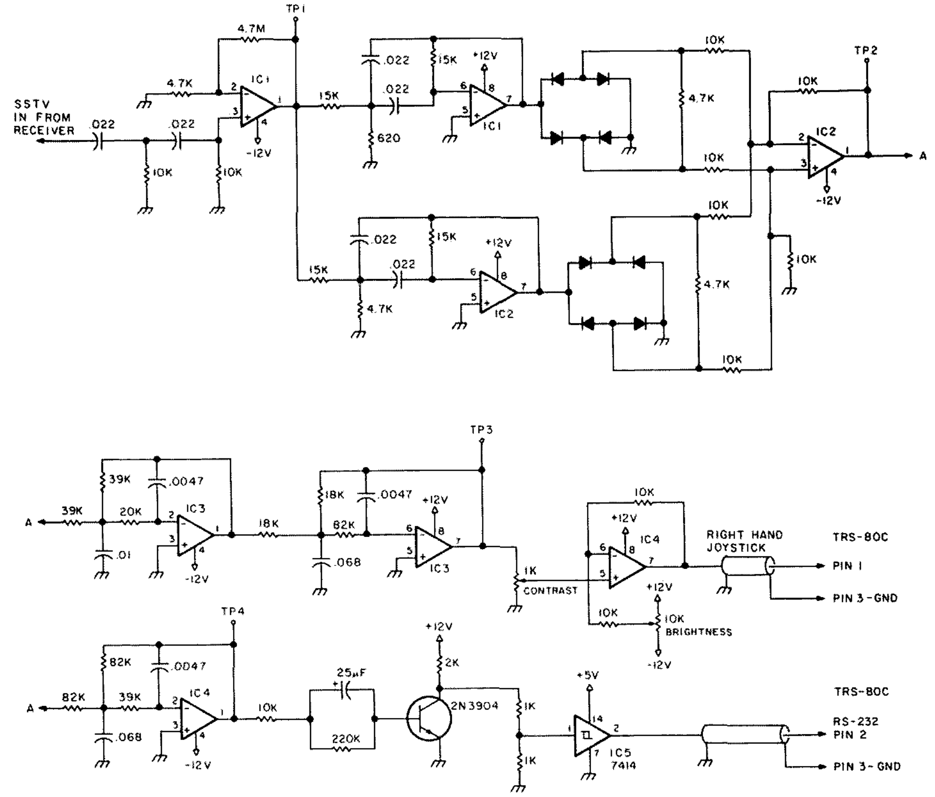

Fig. 4. SSTV/FAX receive demodulator schematic showing a front end which can be used with the computer to display both SSTV and FAX images. The FAX application can be used only on the HF bands.

The block diagram of the display card is shown in Fig. 2 and the schematic is shown in Fig. 3. The following sections describe the major functional parts of the display board.

Display Board

The display board is attached to the expansion port on the side of the CoCo. This port provides connection to the address, data, and control signals of the 6809E MPU. Wiring to the CoCo must be as short as possible; less than one-half-inch leads are a must. The data lines are connected to both the eight RAM ICs and the VDG U18 (6845) display-controller IC through a data bus transceiver (U20). The R-W line determines if the CPU is reading or writing to the board.

In order for the display-controller IC to function, you must first write data to its 18 internal registers. Only three address bits of the 6809 CPU IC are connected to the card. These low-order address bits select the mode which you are performing. The SCS line on the TRS-80C connector is used to select address FF40. The interface E line is the enable signal from the 6809 CPU. This line is used to synchronize the 6845 to the CPU IC for writing to its internal registers.

1. *Functional Selection.* All internal functions of the card are software-selected by a U14 (74LS138). The functions are shown in Table 1 and are described in more detail in the programming section of this article.

2. *Random Access Memory.* This card contains 16K of display RAM (U1 to U8) in eight 2K-by-8-bit ICs. Static RAM was used so as to make the design as simple as possible. Dynamic RAM has the advantage of lower cost but requires extra circuitry to develop RAS and CAS signals, and it is difficult to correct and diagnose problems when they occur. Simple changes can be made to the circuit to add more display memory. Modifications have been made to add 32K RAM. The board can then display 256 pixels on 256 lines, black and white. Television pictures in this mode are starting to approach standard US TV quality pictures.

Control of read or write to the RAM is determined by U25 and U26. During most of the time, RAM is in the read mode. This causes the video data to be valid on the internal data bus. When data is written, it is transferred to and from the CoCo through bus transceiver U20 to the RAM ICs.

3. *Video Display Generator.* The VDG U18 is the heart of the display board. This integrated circuit has 18 registers. In order to make the board operational, the registers must be preloaded before a picture can be displayed on the card. This IC is used to develop the video refresh timings of the RAM. By simply changing the initialization values, either 50-Hz or 60-Hz video can be displayed.

An example of CRT initial-

Fig. 7. Program example for SSTV transmission.

ization is contained in the programming section. The initialization constants were chosen to display an image with the minimum amount of tearing and proper centering on a 9-inch RCA Color Trak TV set. The TV set was interfaced to the video card by a Radio Shack rf modulator.

4. *The Master Clock.* The master clock is a crystal oscillator operating at 6.144 MHz and is generated by a 74LS00 U21 IC. This crystal frequency was chosen to display an active picture time of 42 microseconds. The initialization software of the 6845 is used to fine-tune this display time. A counter is used to divide the clock frequency by 2 and 4.

5. *The Internal Data and Address Bus.* The entire card is designed to display an SSTV picture continuously. Since the card must be powered by an external source different from the computer, power can be dropped on the computer and the display will still be active.

When a picture is to be displayed on the card, the refresh process is interrupted for a few microseconds. This causes a small white line to appear on the display. The direct memory access (DMA) scheme used on the card is very simple in principle. Normally the addressing of RAM is from the VDG through two tri-state buffers, U16 and U17. When the CPU writes to RAM, not-RAM select is brought low and the RAM address is generated by two counters, U10 and U11. At this time, VDG buffers U12 and U13 are floated on the address bus and the counter buffers drive the bus. After the RAM has been written, the counter advances to the next address.

6. *Display Data.* The digital display data is latched from the data bus at the correct time by the 74LS374 U24; the black and white is twice the rate of the color. The 74LS374 U39 is latched from the data bus every 650 nanoseconds. This data is fed to both the black and white and color modulators. A multiplexer is used to feed the black and white modulator. The multiplexer 74LS157 U30 is clocked at a rate of 325 nanoseconds, which is 256 pixels per line of SSTV.

7. *Black and White Modulator.* The black and white modulator is fed from the multiplexer, U30, which feeds first the 4 low-order bits (nibbles) then the high-order nibble. The output of the multiplexer is connected to a simple digital-to-analog converter (D/A) which consists of a transistor and 10 resistors.

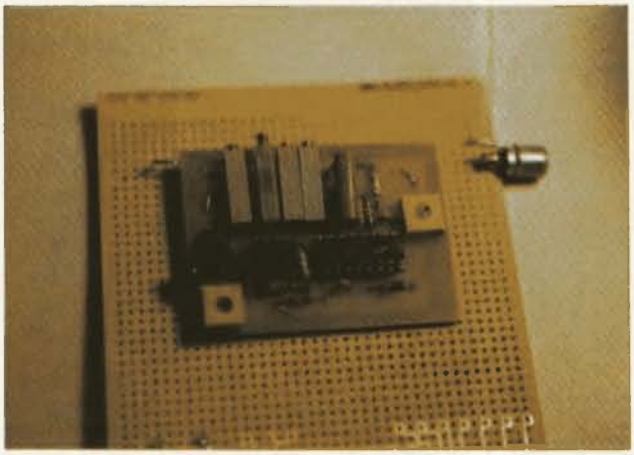

Photo E. RTM Circuit Board's SSTV transmit interface placed on a Tandy prototype card. The card can be plugged into a card cage or a socket for ease of removal and repair.

Sync pulses are generated by the VDG U13, are ORed together by U27, then mixed with video data in the single-transistor D/A converter. Since 4 bits are used, the modulator is restricted to 16 possible gray levels per pixel.

A picture-smoothing capacitor (1000 pF) was placed across the 510-Ohm resistor to ground at the D/A summing point. The value of this capacitor can be optimized to produce the picture most desirable. The absence of the capacitor produces a more digitized picture.

8. *Color-SSTV Modulator.* The color-SSTV modulator consists of three ICs, LM1889 U32, LM1886 U31, and a 9602 U33. The SSTV modulator functions by clocking the picture data on the latch. The data is next transferred to the LM1886 which converts the digital pixels to difference and luminance signals. These signals are internally connected to the color modulator which provides composite color video.

Three additional signals are provided to the LM1886, blanking, sync pulse, and a burst gate. The burst gate is developed from a 9602 which is a dual single shot. The burst gate serves as a reference signal. The location of the burst gate must be adjusted to the correct position on the horizontal-blanking back porch. This is the only adjustment on the board.

Fig. 8. Initialization of the display board; this is an example of how the display board 6845 can be initialized.

The digital data to the LM1886 (U32) is in the format of 3-by-3-by-2 bits of red-, green-, blue-frame information. For example, the lower three bits of the byte are the red-frame information, the next three bits are for the green frame, and the most significant bits are for the blue frame.

This configuration allows for a possible 256 combinations which are unique colors. Since the LM1886 allows for nine bits of digital data to be inputted, the LSB is tied to the MSB of the blue-frame input of the IC to make the bit pattern compatible with the eight-bit display-data bus. This trick allows for black and white images to be displayed. Without this modification, the black and white images would have a blue hue.

9. *TV-Camera Interface.* A number of points are identified in the logic of the display-board interface for the inclusion of a TV camera at a later date. The camera interface will function as follows: When the 74LS00 U9-5 is brought low, the counter will drive the address bus. The TV-camera pixel counter will be incremented by the input U9-9. The RAM read/write is controlled by U26, and the TV-camera input at U25-12/13 will cause the RAM to switch to the write mode. Pixels can next be written to the RAM from the data bus.

Receive Demodulator

The receive demodulator is a device which decodes the SSTV tones into a dc voltage proportional to input frequency and digital sync pulses. This circuit converts video tones of 1500 Hz and 2300 Hz to 0 volts and 5 volts, respectively. A frequency of 1200 Hz converts to a positive digital pulse.

The circuit consists of four stages of filtering and one stage of pulse shaping. Its schematic is shown in Fig. 4.

The decode by this circuit is not only compatible with SSTV but can also be used to decode FAX pictures transmitted commercially on the HF frequencies.

The SSTV video enters the demodulator through the limiter circuit, U1. The limiter is connected to two bandpass filters, U1 and U2, which have bandpasses of approximately 1100 to 2400 Hz. These filters are connected to two diode-discriminator circuits which are combined into a differential amplifier. The signal at TP2 is the carrier frequency of the audio signal with amplitude modulation. The signal in this path with TP3 (U3 and U4) is a series of bandpass amplifiers which allow only the video components of 1500 and 2300 Hz to be passed.

The path of TP4 and U4 is used for the detection and waveshaping of the sync signals. The Schmitt trigger, 7414, is used to develop fast rise times of the sync signals and to produce TTL-level voltages. The sync output from the circuit contains both horizontal and vertical sync pulses.

Modulator Circuit

The modulator interfaces to the CoCo and is the circuit which produces the SSTV audio tones for the transfer of video information in computer memory. The interface, shown in Fig. 5, connects to the CoCo through the RS-232 and cassette-output ports. The cassette-output port is a 6-bit digital-to-analog converter.

The circuit functions as follows. When the RS-232 output is raised, the modulator outputs a sync frequency of 1200 Hz. To generate video tones, a ground

Photo F. A color-SSTV picture displayed on a TI color monitor attached to the K6AEP prototype display board. The picture was received over amateur radio on 28.680 MHz by the TRS-80C and saved on tape. The picture was generated by WB0UNB in St. Louis, Missouri.

Photo G. A color-SSTV picture generated by W0LMD and placed on audio cassette tape and loaded into the TRS-80C. This picture shows the effect of color contouring. Since the display has only 256 possible colors, the shading in the flesh-tone regions are noticeable.

potential is applied to both the RS-232 output and the video input. This causes a video frequency of black 1500 Hz to be outputted. When the video level is increased to approximately 1.1 volts by outputting a digital F to the cassette-output port, a frequency of 2300 Hz is generated. By the use of software, an SSTV picture can be generated by software and transmitted.

The Software

The preceding section provides you with a complete description of the hardware requirements for SSTV applications. Obviously, the hardware performs few useful functions without the software. The intent of the hardware design is to place the burden of all timings and control on the software. This allows for the maximum utilization of all hardware interfaces. There are the following limiting factors.

Microprocessor Speed. The reception or transmission of images is limited by the rate at which the instructions can be executed by the CPU. Fortunately, the 6809 microprocessor is very fast due to its rich instruction set and its ability to process 16-bit data even though the processor is on an 8-bit data bus.

Internal Analog-to-Digital Converter. All of the preceding interfaces are based upon the use of the internal analog-to-digital converter in the TRS-80C. This feature is used to process joystick inputs when playing games. The A/D converter uses a simple successive-approximation technique and is driven by the microprocessor. When this technique is used, the conversion rate is quite slow. The tightest loop which can be written to utilize this feature allows for the conversion of 4 bits of data in approximately 75 microseconds. Even though this is slow, the rate is sufficient to allow for SSTV and FAX reception.

Software Functions

In this section, the software and hardware will be described in a simple, broad, overview approach. The principles described can apply to SSTV, FAX, or any other communications mode which uses a slow rate of transmission or reception. Normally this type of software is called firmware or microcode. Since the software is extremely time-dependent, care must be taken with each instruction written to make the time as short as possible. The description of the software routines will be general enough so that they can be recoded for any general-purpose microprocessor. One important point is that all software must be written in the microprocessor's native assembler language. High-level languages are too slow. Even the most efficient compilers are too slow for SSTV applications.

Receive Software. In Fig. 6 is a simple routine which will receive a picture through an interface attached to the CoCo joystick and RS-232 input ports. The interface can be either the SSTV receiver (Fig. 5) or the FAX receiver (Part II of this article). In both cases the software is identical. The only change in both modes is the delay between pixel reception. The software routines provided are not complete but they do provide an example to readers ambitious enough to learn assembler-language programming. The program functions as follows.

The first six lines of code initialize program constants for the correct number of lines and place the CoCo multiplexer to the correct joystick-input-connector pin. The hardware counter PORT3 is reset to the upper left-hand corner of the picture area. As soon as a vertical sync signal is received on the interface, the program starts to digitize the picture.

The A/D routine converts the analog input voltage to four digital bits and places this information into the lower nibble of a byte. The byte is next placed on the stack, and a software delay is executed. Upon completion of this delay, the next A/D reading is converted. These two values are next added together on the stack, then placed into RAM, and simultaneously displayed on the video card.

The byte in RAM is the same format as the byte on the video card. In the black and white format, the byte

contains two pixels of 4 bits each. In the color format, each byte of the displayed picture has three bits for each color plane except for the blue color. Each time a byte is loaded into the video port, the hardware counter is incremented by one value. This places the DMA address counter to the next location in RAM where the next pixel will be written.

Transmit Software. Fig. 7 contains a simplified example of how an SSTV transmit routine can be written. This example, like SSTV receive, is very general and is provided only as an example to allow for a guideline for development of more complex code.

The software starts off by placing the picture contained in memory onto the display card. This is accomplished by a simple block move of data to the display card. Prior to the block move, the card hardware counter is reset to zero and 16K bytes are taken from RAM and transferred to the video card. Each time the byte is stored at the video-card address, the hardware automatically increments the RAM address to the next location.

The transmission process starts off by issuing a vertical sync pulse. This pulse allows for the receiver on the other end of the transmission path to reset the picture to the top of the screen. In the following steps, a picture byte in memory is loaded into the A accumulator. Each nibble is formatted into the lower nibble of a byte. This byte is next used as an offset to a lookup table in memory which will convert the address to an appropriate digital signal which can be transferred to the D/A converter in the CoCo. This signal will then be transferred to a vco (variable frequency oscillator or modulator) which converts this signal to a sinusoidal frequency in the audio range. This resultant signal is SSTV.

The program continues to transmit pixels until 256 pixels are transmitted. At this time a horizontal sync pulse is transmitted. The program next checks if 128 lines have been transmitted. If so the whole process is terminated. If not, the program continues to transmit pixels.

CRT Controller Initialization. Fig. 8 contains a software routine which will initialize the 6845. The routine takes 16 bytes of data in the table CONCRT and stuffs them into the controller registers. This process is accomplished by first presenting the controller register number to the IC. Next the data byte is loaded into the accumulator then transferred to the card.

The display constants in CONCRT are for a standard 60-Hz display system. To revise the formats to 50 Hz, 625 lines, registers 1 and 5 must be changed. The values should be selected by trial and error.

Hardware Construction

The hardware mentioned above can be constructed on prototype cards or assembled from printed circuit boards. To assemble the display interface on prototype cards takes a lot of work and is vulnerable to errors. Problems experienced with prototyping the card have included: grounds conductors were too small, too few bypass capacitors on power lines, and hardware counters U10 and U11 required a small capacitor on the counter-reset line. Despite these problems, about 5 boards have been constructed to date with excellent results.

Photo A shows the multimode display board.[1] This interface is very compact and its design is slightly different from the one shown in Fig. 3. The board is attached to the computer through a short cable (see Photo B).

Photo C shows the original prototype card constructed by K6AEP. The card was point-to-point solder-wired on a prototype SS-50 computer interface card. A small adapter card was constructed to plug into the CoCo expansion interface. (An etched PC board or completely assembled version of this card is available from L. W. InterFace.[3]

The SSTV receive and transmit interfaces are available in a number of forms. Photo D shows the multimode receive-board interface card; Photo E is a transmit interface from RTM Circuit Boards.[2]

All boards can be placed in a cabinet with the appropriate power supplies of 5 volts (1 Amp) and ±12 volts (100 mA). Cables can be made to attach to the computer and receivers.

Part II of this article will describe the FAX hardware.

Conclusions

The computer approach to displaying images is a very cost-effective method. Most alternative methods available are limited in function and are considerably more costly. The commer-

cial units have one advantage in that they can be purchased and plugged into the wall and they are operational. The computerized system described takes a little more work, but it is extremelv flexible and not subject to obsolescence as are its commercial counterparts. The results achieved with the system described here rivaled those of commercial counterparts.

Photo F is a typical color image, 128 pixels per line on 128 lines, 256 colors per pixel. Photo G is another color-SSTV image which shows the resolution of the display board on facial flesh tones. This type of image is the hardest type to display. This picture shows color contouring due to the 256 colors per pixel. Photo H is another color picture with computer-graphics overlays generated by software. The picture is the same as Photo G but reduced in size by one half. The colored image was moved to the center of the display screen and graphical characters of various colors were distributed around the picture.

Photo H. A color-SSTV picture with graphics. This picture is the same as Photo G, but reduced in size by software and placed in the center of the image area. The graphics were generated by software and placed around the picture. The graphics and picture were all generated by the K6AEP SSTV 7.6 Revision 2 program.

Better results can be achieved with 32K of display memory, but photos were not presented in this article for this mode. The black and white images developed by this display density approach fast-scan TV quality.

More photos will be presented in Part II of the article, on the FAX application.

Obviously a project of this magnitude is not a one-person effort. Some of the people who contributed were Ron Adair K5HFT of Multimode Corporation, Bob Blackstock WB5MRG who helped with the display-board design, Larry Fritz AG8O of L. W. InterFace, and Bob Wilson WBØRTM of RTM Circuit Boards. ■

Wrap Up TVI

Can you endure another evening without transmitting? Use this simple cure to choke out television interference forever.

One of the most perplexing problems for the amateur can be TVI complaints. It seems that no matter how clean your rig, how little power you radiate, or what operating hours you choose, it is only a matter of time before a TVI problem comes home. The best defense against these complaints is the ability to prove you are not ruining your own TV reception. The unfortunate fact of this defense is that few of us can boast of "clean" TV reception while running our transmitters.

After collecting some TVI complaints, most from my own household, a solution to the problem was sought. The original attempt to cure our own TVI problem was the installation of cable TV. This failed miserably and, in fact, enhanced the sensitivity of both television sets to my transmissions. Now, with the capability of jamming every channel day or night, an ultimatum was issued: cure the problem or find another hobby.

Several solutions were tried. The addition of high-pass filters seemed to have little effect on the interference. A new grounding system was installed utilizing multiple copper rods with a braided-copper ground strap run to the rig. This lessened the TVI but did not cure the problem.

Since my efforts were proving less than effective, current literature on TVI prevention was avidly read during my nonoperating time. Despite being hooked up to cable TV, the symptoms appeared to be the result of front-end overloading of the TV receivers. Further reading indicated the probability of inductive coupling between the TV coax and the transmitter. In this case, rf currents are induced to flow in the shield of a coaxial cable situated near a transmitter or antenna. A high-pass filter

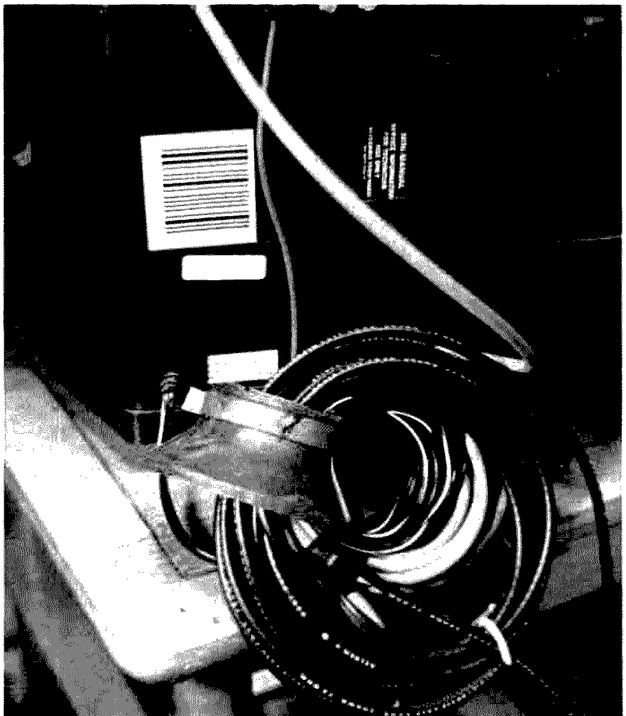

Photo A. The TVI cure in place. The antenna coax and TV power cord are wound in opposite directions through the core to minimize coupling effects.

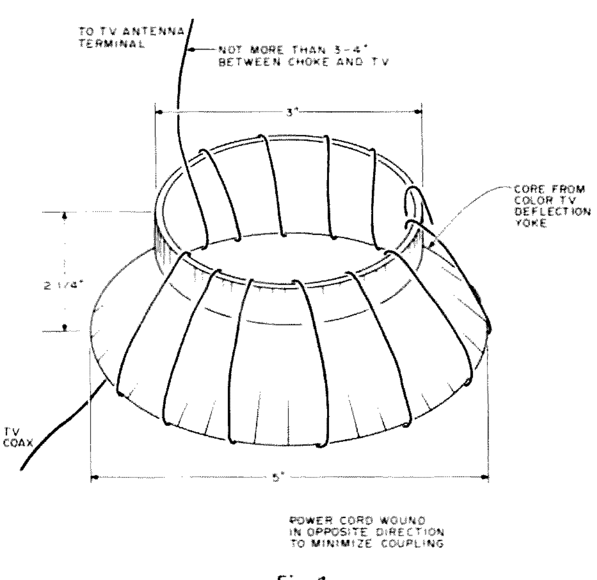

Fig. 1.

is of no use in this situation since the rf current flows down the shield of the coax, through the filter casing, and into the TV.

There are several possible solutions. One is to install a quarter-wave stub at the antenna terminals of the TV, but this is effective for only one operating frequency. A better method is to use a large ferrite toroidal core and wind the coax around it. This functions as a shield choke, preventing rf currents from flowing into the TV, and is effective at all operating frequencies. The only problem with this arrangement is the cost of a suitable ferrite core. They are typically $10.00 to $15.00 apiece.

A less-expensive alternative was sought. Remembering that picture-tube deflection yokes have a toroidal core, several were picked up from a local TV repair shop. They were obtained free of charge, being defective units that had been replaced. The copper windings were stripped off revealing a large, bell-shaped split core bound together with a metal strap. The TV coax was coiled around this core in the same manner as winding a toroidal transformer (Fig. 1). Three inches of cable was left free for attachment to the television. This placed the homemade choke as close as possible to the TV antenna terminals to minimize unwanted rf pickup.

The results were truly gratifying. With the transmitter running at full power, only a faint cross-hatching could be discerned on the picture. Next, the television power cord was wound around the ferrite core in the same manner as the coaxial cable. At this point, all symptoms of interference vanished. Even with one television operating a mere four feet from the transmitter, the picture and sound remained crystal clear.

The same setup was tried with the stereo system in an attempt to achieve the same spectacular results. The speaker leads and the power cord were wrapped around the core in the same manner as with the television. Again it worked beyond all expectations. "CQ CQ from KR7L" was never heard on it again.

This system will not cure every TVI or RFI problem you might have. If your transmitter is spewing out harmonics or other spurious radiation, you need to go to work on the rig, not the television. On the other hand, this method will cure simple overload problems and the cost can't be beat. The TV repair shops in my area were more than happy to give away all their old, defective deflection yokes.

Now when the neighbor comes over to announce that I'm pulverizing his TV, I set him down in front of mine while I fire up the rig. A short demonstration results in profuse apologies and a willingness to listen to some solutions. In addition, I can rest assured that I am free to operate when and where I choose without disrupting the family's favorite TV programs. ■

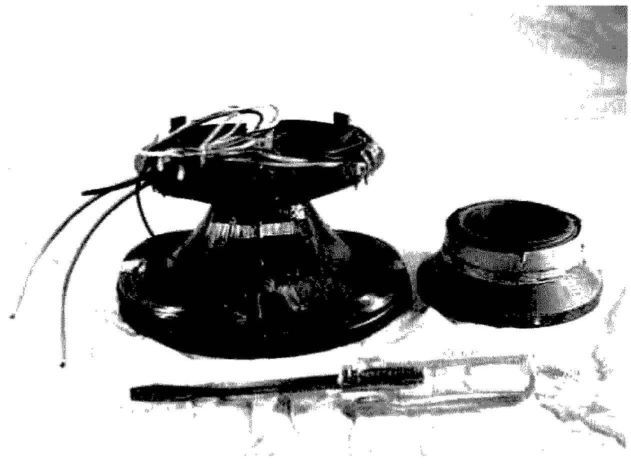

Photo B. The ferrite core is removed from the deflection yoke by releasing the metal restraining band or by cutting the masking tape that holds it in place.

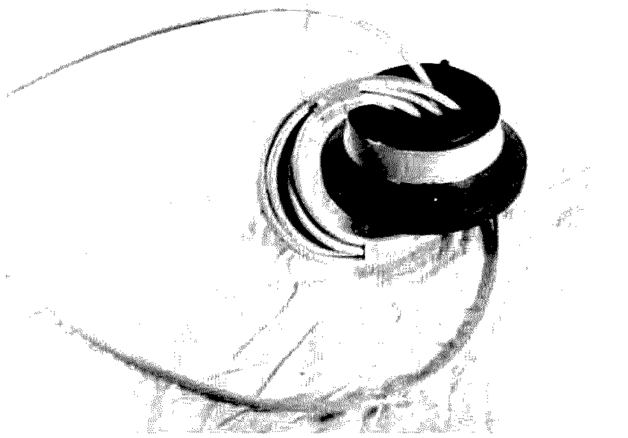

Photo C. The correct method of coiling the TV coax through the ferrite core.

But I Know How To Solder!

Anyone can dribble hot metal over a joint, but it takes an artist to really solder. Are you a Picasso or a pig?

Do you? Do you really know how to solder? We have all seen good and bad soldering in commercial products, from the small battery-operated AM radios and their atrocious workmanship to high-quality and reliable products both domestic and foreign. Most of the amateur-radio equipment manufacturers have rigid quality control which ensures that you are getting a good product.

But how about you? Can you duplicate their results when you work on that home project? And when it's finished, do you stand back and look at it with a feeling of accomplishment or do you say "good enough for government work," as long as it works?

Then and Now

Let's look at this process of joining two pieces of metal together by the use of a solder alloy. It's one of the oldest known joining techniques and probably the least understood by most hams. Believe it or not, it was first developed in ancient Egypt; the technology has advanced to such a degree today, however, that even to mention its origin would be like comparing the first crystal set to the modem-day receiver.

Today, in the field of electronics, soldering is far from the simple task it was in the early days of radio. It could be considered a fine art and one that requires experience, a thorough knowledge of fundamentals, and great care. Faulty solder joints still remain the chief cause of equipment failure.

What is presented here will cover *basic* soldering for electronics and certainly does not represent the details which should be covered for one to become skilled. It should provide you with the fundamental knowledge needed to perform soldering operations with a fair degree of reliability. It will cover the fundamentals of solder action, the selection and proper use of the soldering iron, and some clarifying definitions. It will not cover the accepted procedures for soldering wires and components to single-sided, double-sided, and multi-layer circuit boards.

All aerospace contractors have in-house training programs that are a certification requirement imposed on them by NASA. These go into great detail and are quite lengthy. To cover these related requirements would fill a book, but the average amateur has no use for information on a "PWB lapped termination, a PWB stud termination, PWB clinched termination, turret terminal termination, or a bifurcated terminal termination." This subject can get very dry after about a week, and just a little bit goes a long way.

So, the key word here is *reliability*. High-reliability soldering has been an answer to early failures in space equipment and the

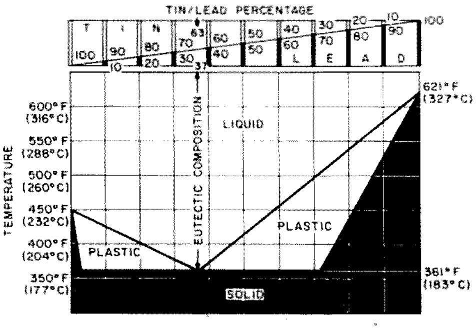

Fig. 1. Fusion characteristics of tin/lead solders.

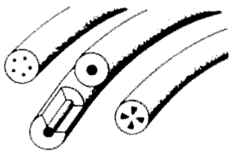

Fig. 2. Types of cored solder, with varying solder-flux percentages.

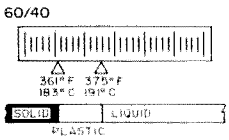

Fig. 3. Plastic range of 60/40 solder: Melt begins at 361° F and is complete at 375° F.

concept has spread to include aviation, weapons, and medical equipment. Today, we expect this reliability in every-day electronics as well, from your hand-held to receivers with complicated bells and whistles.

General Considerations

In order to form a continuous electrical path that will ensure a good contact, one that vibration and mechanical shock won't loosen and will not be subject to oxidation or corrosion, we must solder it according to accepted standards. Look at Fig. 1; it details the fusion characteristics of tin/lead solders. Notice the melting point of lead and tin and their different alloys. These will be discussed later in more detail.

The term "soldering" generally means "soft soldering," which simply means a method of joining two metals together with an alloy of relatively low melting point, usually composed of tin and lead.

Common soft solder used by all of us at one time or another comes in ribbon, wire, and bar form. Wire solder may be either solid or tubular with a core (or cores) of either acid or rosin soldering flux. Bar solder is always used with heavy irons or with blow torches, plumbing, and large sheet-metal work. Ribbon and wire solder are used with light irons on electrical wiring and other small jobs, as shown in Fig. 2.

Solder is designated by numbers; the first number represents the proportion of tin and the second number the proportion of lead. 60/40 solder means a solder that is composed of 60% by weight of tin and 40% by weight of lead. A common solder for all-around use is 50/50 or "half and half." There are others for a more specialized use. Soft solders for gold and silver and for copper and brass sheet generally contain more tin than lead and melt at a low temperature.

So-called liquid solders, or "cold solders," usually are not solders at all but are cements or glues fortified with aluminum or other metallic powder. Avoid trying to make a metal-to-metal bond with these products. They are not electrically conductive and they may disintegrate in the presence of organic solvents or at temperatures considerably below the softening point of tin and lead solders.

The Need for Fluxes

What does the application of flux do? Why do we need to apply flux to a surface to be soldered? In order for the solder to adhere to the metals to be joined, the surfaces must be completely free of oxide. Oxides are present on most metals; they form at room temperatures but almost immediately when heated. A coating or some material must be used that will remove the film already present and protect the solder and the metal from further oxidation. Such a material is flux. It is a Latin word, and it means "to flow."

Except for electrical work, the fluxes most commonly used for soft soldering are solutions of pastes that contain zinc chloride or a mixture of zinc and ammonium chlorides. The heat of the soldering operation evaporates the medium containing the chloride flux. The flux then melts and partially decomposes with the liberation of hydrochloric acid which dissolves the oxides from metal surfaces. The fused flux also forms a protective film that prevents further oxidation. These fluxes are called "acid fluxes" and come in both liquid and paste form.

It goes without saying that acid fluxes have a corrosive action and most certainly should not be used to solder electrical connections. On printed circuit boards—and if it is necessary to wipe the surface with flux prior to soldering—it would certainly be wise to use a good grade of flux and one that can be removed completely.

Some assembly procedures recommend that all solder pads be wiped with a coat of flux. This is a bad practice. It is hard enough to remove the last traces of excessive flux and its residue without damaging the printed circuit board or the installed components. If there is adjacent wiring attached, there is always the danger of rosin flux wicking into the wire between the conductor and the insulation, which would not be removed when the board is cleaned.

Always use a good grade of solvent to remove the unwanted flux and its residue. Ethyl alcohol, isopropyl alcohol, trichorotrifluoroethane, or tricholoethane can be used. A mixture of about 90% isopropyl alcohol and 10% naphtha is excellent for most work.

An acid brush with about half of the bristles cut away makes an effective tool to remove the flux and residue. Rub gently but firmly, taking care not to press too hard, until all traces of the flux are removed. In some cases the joint can be polished using several thicknesses of Kleenex.

Solder

Rosin core solder, when heated to its melting point, undergoes several changes which should be noted in order to make a good joint. It is solid to begin with, changes to a plastic, and then changes to a liquid form. Pure tin melts at about 450° F and lead at 621° F. It would seem that a 50/50 alloy would therefore become liquid at about 535° F. Not so. 50/50 is a solid until it reaches a temperature of about 361° F. At this point it

See List of Advertisers on page 88

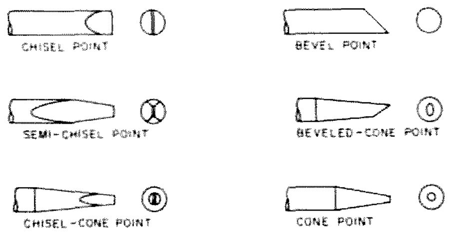

Fig. 4. Tip types.

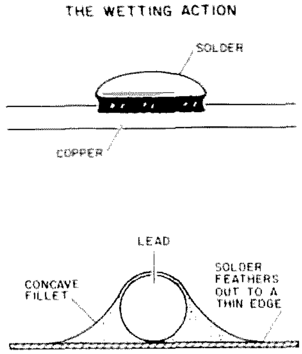

Fig. 5. Molten solder dissolves and penetrates a clean copper surface forming an intermetallic bond.

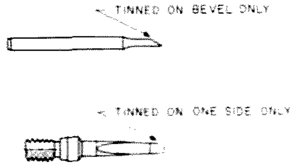

Fig. 6. Selected tinning.

becomes plastic and remains in this condition until it reaches 415° F when it becomes liquid.

Let's take 60/40 (see Fig. 3). At 361° F, 60/40 changes from a solid to a plastic and remains in that state until 375° F when it turns into a liquid. The time that 60/40 remains in a plastic form is considerably less than the 50/50. If the joint is moved while the solder is in a plastic state, it could well be described as a disturbed joint. It might check out with your meter, but when an electrical load was applied, it could fail to conduct.

Let's take another case: 63/37 alloy. This is what is called an eutectic (low melt) composition. It is 63% tin and 37% lead. It has no plastic state and is transformed from a solid to a liquid at 361° F. 63/37 is most generally used on printed circuit boards. It can be seen that this would have an advantage since the plastic state does not occur. Also, the importance of the soldering-iron tip temperature suddenly takes on a new meaning.

Heat Sources and Tinning

A temperature-regulated soldering iron is a must when soldering printed circuit boards. A 50-Watt iron can easily be regulated with a variac or a homemade voltage regulator using a light-dimming rheostat. The temperature can be adjusted to suit the need of the joint to be soldered. The larger the mass, the more temperature will be required. Start with a low temperature and gradually increase it until the desired result is achieved.

The geometric shape of the soldering tip controls the rate of heat flow to the extreme point of the soldering tip. Two main considerations should be made in choosing a proper tip point: access to the solder joint and maximum *wetted* contact of the tip point with the joint members to be soldered. Because of high component density, one often is restricted to just one or two shapes. The standard soldering tips are shown in Fig. 4.

Let's look at Fig. 5 and consider that word "wetted." Wetting is the flow and adhesion of a liquid to a solid surface. It is characterized by smooth, even edges. In other words, a tip that is hot and tinned and ready to do its job. Conversely, de-wetting is a condition in a soldered area in which the liquid solder has not adhered intimately to the joint or, in this case, the solder tip.

Selected tinning (Fig. 6) is an important consideration in certain soldering operations and the point should be tinned on one side only. There is a good reason for this: There is less chance of disturbing an adjacent joint with the immunized side of the tip's point. When a soldering iron is removed from its holder, the soldering tip should be cleaned on a wet, sulfur-free cellulose sponge. The wet sponge will provide a thermal shock to break free and remove secondary oxides from the surface of the tip.

A tip will de-tin or de-wet, and degradation (or the start of oxidation) of the tinned areas will start when the solder begins to ball up on the tip. Once this action has started, it usually will continue until the tip will no longer wet with fresh solder and makes a dry contact with the work. Then the operator will believe the iron is not hot enough. This can all be avoided if the tip is tinned after each soldering operation and prior to placing the iron in its holder.

Another cause of de-tinning is an excessively high tip-idling temperature at which the solder oxidizes faster than you are able to replenish the tip with fresh solder. At high temperatures the flux usually burns and carbonizes, further adding to the de-tinning of the tip. Two simple axioms should be remembered:

1) Solder at the lowest practical temperature, and
2) Keep your soldering tip tinned.

Stranded wires may be tinned very simply if you keep in mind the mass they present to the soldering iron. In other words, the larger the wire, the larger the soldering iron. For example, suppose we wanted to tin a 22-gauge wire and a 14-gauge wire. Both could be handled the same way, with a couple of exceptions. A small, 25-Watt iron with a tip temperature of about 500° F would be sufficient for the smaller wire. However, in order to tin the larger wire, an iron of at least 100 Watts should be used but with the *same* tip temperature.

To tin, place a drop of solder on the tip, place the wire in the solder, and add solder to the top of the wire so that it sweats completely and through the strands. Move the wire slowly along the length to be tinned while adding solder constantly until the strands are thoroughly wet with solder.

Another way to tin wires is called the "reflow" method. Tin your wire in the usual way and note if it has surplus of solder on the wire and separate strands cannot be distinguished. Reflow can be accomplished by raising the iron temperature considerably, then dipping the soldered portion of the wire into flux (a good grade of rosin flux) while wiping the tip rapidly on a wet sponge to shock off the oxides. Very quickly hold the wire in a vertical position and place the tip of the wire on the soldering-iron tip. The excess solder will be removed and will flow to the soldering-iron tip, and the wire strands will be visible. The wire will be thoroughly tinned and will not "birdcage" when bent.

A Word to the Wise

Use a thermal shunt or a heat sink whenever installing heat-sensitive components like transistors, flat paks, or integrated circuits. It is very easy to damage these items with excessive heat. When trimming transistor leads for installation on your favorite PC boards, grip the lead to be cut with needle-nose pliers between the transistor case and the

point where you cut. The energy that makes the unused end go flying across the room can also be expanded in the opposite direction and can fracture the connection inside the housing easily . . . scratch one transistor.

Definitions

Cold solder joint: An unsatisfactory connection resulting from de-wetting or movement of the conductor during cooling. Also caused by too rapid cooling (like dousing it in water). These joints usually appear frosty and granular. They will show up as an intermittent when you least expect it and will drive you up the wall. When checked with your trusty meter, they show good continuity, but when an electrical load is applied, things will change from time to time.

Plated-through hole (PTH): An interesting thing to look for on printed circuit boards. This is a plated-through hole formed by the deposition of metal on the inside surface of the hole. (Also known as a supported hole.) It is used to provide additional mechanical strength to a soldered termination and/or to provide an electrical interconnection on a multilayered printed wiring board. Use extreme care whenever removing a component from one of these. You could loosen it up on one side and it would still be solid on the other side. It is best to use solder wick here or a solder sucker and remove all the solder.

Rosin solder joint: A connection with entrapped rosin flux. The only recourse is to re-solder—carefully.

Solder icicle: Most generally noted on small imported hand radios. It is a cone-shaped peak or sharp point of solder usually formed by the premature cooling and solidification of solder upon removal of the heat source. High-speed production causes this unsatisfactory condition. If the operator worked that fast, it makes one wonder what other bad practices he was guilty of. Be suspicious of the whole unit if this is noted.

Things to Remember

- Flux is very corrosive at solder-melting temperatures, which accounts for its ability to remove oxides. If you must use flux, use a good grade. Kester No. 1544 is a good grade for almost all electrical and electronic soldering.
- Vary the voltage input to your soldering iron and thereby control the tip temperature. Also choose a soldering iron that is matched to the thermal mass you wish to solder. Light work, light iron; heavy work, large iron.
- If the iron tip is too large for the work and too hot, the heating rate will be so fast that it cannot be controlled. If the tip is too small, the heating rate will be too slow. A good rule to prevent overheating is to *get in and out as fast as you can*. This simply means using the hottest iron you can react to, or one giving about a two-second contact on the joint being soldered. Caution: Too much heat, too much pressure, too many times on a printed circuit board—even on the very best board—will lift the pad.
- Always remove the flux and other impurities. Keep it clean . . . clean . . . clean!
- Finally, some soldering irons are simply not compatible with transistors and integrated circuits. They are not isolated from ground and can easily zap everything you solder. Choose well.

I would like to acknowledge the encouragement and help of Merv Holmberg KQ1G. His constructive comments and enthusiasm made research a pleasure. ■

Free-Form Filter Design

Build the ultimate audio filter: high-pass, low-pass, bandpass, notch, variable Q and cutoff frequency, all in a single circuit. Circuit? Sorry, that's single chip!

Jonathan A. Titus KA4QVK
PO Box 242
Blacksburg VA 24060

Many hams use filters to block interfering signals so that CW, phone, and RTTY transmissions can be copied better. Crystal filters are used in many modern transceivers in i-f stages, and add-on audio filters are available from many manufacturers. Most audio filters don't vary much in their design, using operational amplifiers (op amps), resistors, and capacitors to put together active-filter building blocks. These have been described in many publications, and a typical filter is shown in Fig. 1. Common audio filters are low-pass, high-pass, bandpass, and notch. See Fig. 2 for typical frequency response curves.

Circuits are available if you want to build your own filter. Articles in *73*, *QST*, and other ham magazines as well as sections in *The Radio Amateur's Handbook* provide circuit details.[1,2,3,4,5] Most of the parts are inexpensive and readily available, but if you want to look at off-the-shelf filters, they are available from many manufacturers. The MFJ-720 is a typical bandpass filter, centered at about 750–800 Hz. Standard filter circuits can be duplicated, and by using several filter stages in series, you can get a fairly narrow bandwidth. You also can buy a filter such as the M and M Electronics MSB-1, which contains all of the filter types. Even more complex and expensive filters, such as the Datong frequency-agile audio filter, are available.

Integrated-Circuit Filters

If you decide to build your own filter circuits, you might consider using the AF-100 integrated circuit from National Semiconductor. This "chip" contains three op amps preset in a basic filter circuit. By adding a few external components, bandpass, low-pass, and high-pass filters can be built. A "spare" op amp in the chip is used if you want to build a notch filter. Filters are easy to set up; a few calculations are needed to select the right combination of resistors and capacitors, but the math is simple. There is a 20-page data sheet available that explains the types of filter functions that can be obtained, and several examples show how to use this filter chip. There is also an AF-150 universal wideband active filter and an AF-151 dual universal filter.

One of the limitations of most of the standard filters is that you can't easily change the cutoff frequency once the filter has been built. For example, in a filter with four op amps, you would need to carefully vary at least four resistors to change the cutoff frequency.

By the way, the term cutoff frequency is used a bit loosely, since low-pass and high-pass filters have a cutoff frequency, while notch and bandpass filters have a center frequency. Since it's cumbersome to say both,

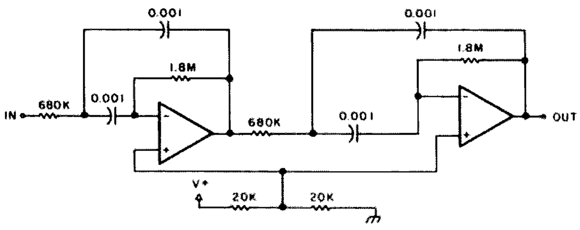

Fig. 1. A typical op-amp bandpass filter for 750–800 Hz.

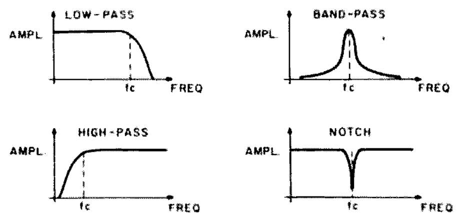

Fig. 2. Frequency response curves for standard filters.

let's use cutoff frequency, since it's fairly standard.

If a CW signal is being masked by one at a slightly higher audio frequency, you may be able to shift the interfering signal a bit higher and then use a bandpass filter to add further selectivity to the signal you are copying. If the cutoff frequency of your filter is fixed, this type of adjustment may be difficult. Many less expensive filters have a fixed cutoff frequency, while some of the more expensive ones, such as the M and M Electronics MSB-1, use ganged potentiometers so that the center frequency can be varied. Ganged pots get to be expensive, so designs are generally limited to two pots operated by the same knob. Since ganged potentiometers don't always track one another perfectly, filter performance is affected.

The Bencher XZ-2 bandpass filter has a variable cutoff frequency, but ganged pots are not used. A single potentiometer controls several transistors that act as variable resistors in the individual filter stages. This allows the center frequency to be changed rather easily, and it seems to be a reasonable solution to the mechanical problems of ganged potentiometers.

CW Regenerators

A CW regenerator is a fairly simple circuit in which a phase-locked loop (PLL) or other tone-detecting circuit is used to pick out a narrow frequency band.[6] Since the *output* of the PLL is a logic signal indicating tone or no tone, the CW signal being received is tuned so that the PLL "follows" it. An LED on the output provides a visual signal that can be used to show you when the PLL is accurately tracking the CW signal you are hearing. The output of the PLL is used to trigger an oscillator, and this tone is heard in a headset or on a speaker.

The net effect is to "reconstruct" the signal by having a narrow tone bandwidth detected and using this to generate a perfect tone for the listener. A CW regenerating unit called the Amcoder was available from AMC Engineering a few years ago, and a block diagram of this unit is shown in Fig. 3. Since PLL circuits are sensitive to the amplitude of the input signal, an agc stage between the receiver audio output and the PLL input is recommended.

Another CW regeneration circuit was described in *QST*.[7] This makes use of an "envelope detector" that demodulates the CW tones and triggers an oscillator to regenerate a perfect tone. This circuit also incorporates a delay so that noise spikes do not trigger the tone oscillator.

Many other types of filters—LC, RC, acoustic, etc.—have been described by amateurs and professionals.[8]

Switched-Capacitor Filters

During the last year or so, a new type of filter integrated circuit has come on the market. This is called the *switched-capacitor filter*, or SCF, and several types are available. Among the easiest to use is the National Semiconductor MF-10 SCF.[9] It costs about $3.00 and can be set up easily to perform any of the four filter operations. No external capacitors are needed, and only a few external resistors are used. There are two filter circuits in each MF-10 integrated circuit. Without going into the theory of operation, I'll just tell you that the cutoff frequency of the MF-10 filter chip is set by using an external clock. The clock frequency is selected to be either 100 or 50 times that of the cutoff frequency of the filter you are designing. The 100/50 ratio is preset at one pin on the MF-10 chip. Since this is just a logic-state input, it provides an easy way to change the range of the filter. Either a CMOS- or a TTL-compatible clock signal may be used.

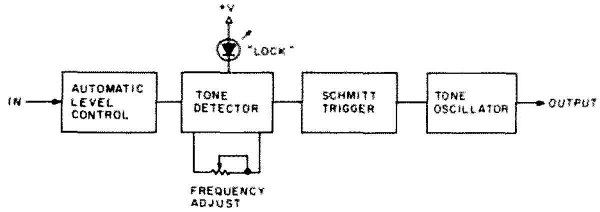

Fig. 3. Block diagram of a CW regenerator.

If you want to use the MF-10, you can set it up for a particular type of filter and vary the cutoff frequency of the filter by varying the clock frequency. One problem with all SCF circuits is that a small amount of clock signal is superimposed on the audio signal being filtered. However, since the clock frequency is so much higher than the audio signal, one, you won't be able to hear it, and two, it's easy to put a simple RC low-pass filter in the final audio output circuit to remove most of it. A typical fourth-order, 1-kHz low-pass filter is shown in Fig. 4.

In this circuit, both filter circuits in the SCF chip (each of which is a second-order filter) have been used in series. Using a common clock frequency for all of the filter stages lets you easily change the center frequency of the filters, and they all track one another without significant errors. Additional information about the MF-10 is found in the 12-page data sheet for this device.

Two other SCF devices are the Motorola MC145414 dual tunable low-pass filter and the MC145433 notch filter.[10,11] These devices were designed for use primarily in data communications equipment and modems, but they can be adapted for amateur use. They are a bit expensive, in the $10 to $20 range.

The Reticon R5620

I have found that the most interesting SCF is the R5620, manufactured by EG & G Reticon and available for about $7.50. This filter has built-in high-pass, bandpass, notch, and low-pass operations, and no external filter components are needed. All of the filtering is done on the chip with built-in circuitry. The EG & G Reticon Company manufactures linear photodetector arrays

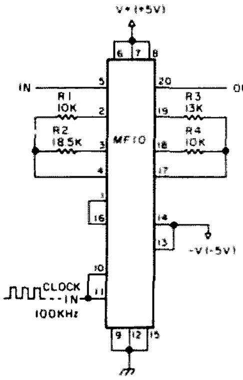

Fig 4. Using an MF-10 filter chip for a 1000-Hz, fourth-order, low-pass filter.

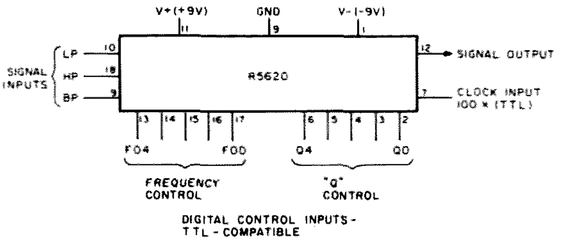

Fig 5. Pin configuration of the Reticon R5620 SCF chip.

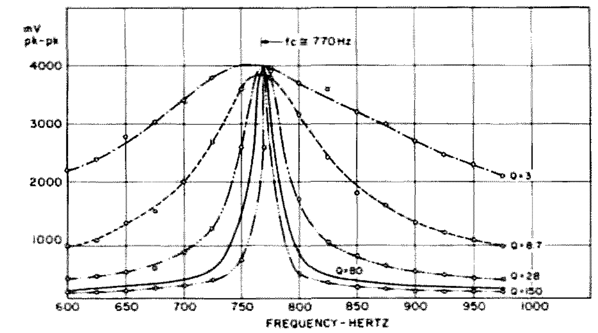

Fig. 6. Response curves for the Reticon R5620 used as a bandpass filter.

and x-y photodetector arrays that are used in solid-state TV cameras. They also produce very complex and expensive filter devices for special signal-processing applications.

In a filter circuit that uses the R5620, the cutoff frequency and its Q are independently set by providing five binary (logic 1, logic 0) inputs for each function. This means that there are 32 independent settings for each one. Any one of the four filter actions can be selected. Except for a few resistors on signal inputs, no other external components are required. A pin configuration diagram of this chip is shown in Fig. 5. This chip uses a split +9-volt power supply and an external clock signal. The clock signal can be TTL-compatible, but it is also easy to build a clock circuit that will run from the +9-volt power supply.

The center frequency of the R5620 filter can be changed by changing the clock frequency or by changing a 5-bit binary code applied as logic levels to five pins on the R5620 chip. It is this set of digital inputs that gives the R5620 a great deal of flexibility. The five digital inputs are labled FO4–FO0 and they are shown in Table 1. The clock rate is listed as the ratio of the cutoff frequency to the clock frequency. The control inputs are simply provided as a 5-bit straight-binary code. Let's look at an example. We'll assume that a 100-kHz clock signal is used and that the ratio of 102.3 has been chosen by setting FO4–FO0 to 01111. The filter's cutoff frequency is 978 Hz.

If the 100-kHz clock signal is used, the filter's cutoff frequency can be varied from 500 Hz to 2 kHz by varying the 5-bit binary code on frequency-control lines FO0–FO4 between 00000 and 11111. The 32 frequency steps are logarithmic, which simply means that the frequency ratios are fairly even, about 4 to 5% per step.

The alternate approach is to preset the 5-bit frequency code for the R5620 at about its mid-frequency setting (10000) and then vary the frequency of the clock signal controlling the filter. Without careful clock-circuit design, this can present problems. Many home-brew clock circuits spread out the low frequencies on one side of the frequency-controlling potentiometer, but high frequencies are "scrunched" at the other side. Using a fixed clock frequency and changing the 5-bit control input seems the better method of frequency control.

The Q of the filter also can be varied by using the five digital inputs labeled Q4–Q0. As shown in Table 2, the Q can be varied from 0.57 to 150. That's right, 150! Of course, you're not going to get much useful information through a bandpass filter with this high a Q, but in between 150 and 0.57 there is a lot of useful filter power. Typical bandpass response curves are shown in Figure 6.

The R5620 has three signal inputs, LPin, HPin, and BPin, and by connecting the audio signal to be filtered to one of these, the appropri-

ate filtering is done. When the notch filter is to be used, the audio signal is routed to both the LPin and the HPin inputs. The chart in Table 3 shows how the signals are connected. There are other combinations of these three inputs, but they are not useful for filtering.

Since the R5620 has a 0-dB insertion loss, no external signal amplification or attenuation is needed. However, if you want to use this filter between your receiver and headphones or a speaker, an audio output amplifier is recommended. There are many of these in integrated-circuit form, and they are easy to use.

The R5620 filter circuits can be cascaded, and you can control each one separately or you can use parallel digital inputs and control them simultaneously. The next question is how to get a 5-bit binary code.

Digital Filter Control

One of the obvious ways to generate the 5-bit code is by using a series of five on/off or logic 1/logic 0 switches. This may be fine for testing, but for on-the-air use, it's impractical. Thumbwheel or rotary switches provide an alternate, but most of these are limited to 12 or 16 positions. There are lots of 40-position binary-coded rotary switches available from old 40-channel CB units, but these use an odd type of binary code, so they can't be used easily to generate the required 5-bit straight-binary code.

A solution that isn't as obvious is to use an analog-to-digital (A/D) converter to generate the binary codes that are needed. An A/D converter has a minimum and a maximum voltage range, and when an "unknown" voltage is within the range, the converter will provide you with a binary code that represents the unknown voltage. Thus, for an 8-bit converter, the range of measurable voltages might be between 0 and 5 volts, with the binary outputs being 00000000 up to 11111111. Computers and other digital devices use A/D converters to measure unknown voltages.

The National Semiconductor ADC0804 8-bit A/D converter was chosen because it is easy to use, readily available, and inexpensive. It is used in a free-running mode, so that conversions are done one right after the other. A potentiometer is used to provide the voltage input, and the A/D converter provides an 8-bit straight-binary output, as shown in Fig. 7.

This circuit provides an 8-bit output that goes from 00000000 up to 11111111, from one side of the pot to the other. The function is the same as that of a 256-position binary-coded rotary switch. Not bad for about $4.00. Since only five bits are needed, the most-significant five bits, D7–D3, are used. The other three bits, D2–D0, are not used. This arrangement provides for 32 binary codes, linearly spaced across the range of the potentiometer. The ADC0804 chip has a fairly low input impedance, so a low-value potentiometer must be used to provide the unknown voltage that is to be converted into a binary code.

A rotary switch with four positions and three poles is used to route the input audio signal to the correct inputs for the four filter actions. This is shown in Fig. 8.

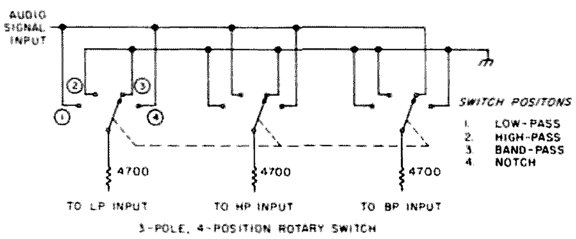

Fig. 8. Schematic diagram of the filter control switch.

A complete filter circuit is shown in Fig. 9. You can cascade as many of these stages as you want to and put them together in various combinations. For example, you might have two filters in series. Both could be set up for low-pass operation, providing a fourth-order low-pass filter. Or you could set one for low-pass operation and the other for notch operation. Of course, the audio output amplifier is only needed at the end of the filter chain.

Using the Filter

There are many uses for a

versatile filter, particularly since all of the basic filter operations are available on one chip. Since the cutoff frequency and the Q can be varied, this type of filter is useful for SSB, CW, and RTTY operations.

For example, if you are using a Bell-202-compatible modem, you'll be using tones of 1200 and 2200 Hz. You can build a switched-capacitor filter for each frequency, deriving the clock signal from one common crystal. The frequency would be 1200 × 2200, or 2.640 MHz. Since the filter's clock frequency must be 100 times the center frequency of the signal being filtered, dividing the 2.640-MHz clock by 22 and by 12 gives the proper clock signals for the two filters: 120 kHz and 220 kHz, respectively.

In this application, bandpass filters would be used and the cutoff frequency controls would be preset. The Q of both filters could be set in parallel by a single control or each could be set separately.

A filter-and-monostable RTTY demodulator is described in the 1982 edition of *The Radio Amateur's Handbook*,[12] and several SCF circuits could be used in place of the op-amp-based active filters. Using SCF circuits allows the filter characteristics and frequencies to be easily changed.

Switched-capacitor filters provide an alternative to op-amp-based filters in many ham-radio applications. They are not much more expensive than the classic circuits, particularly when you consider their flexibility and the ease of designing circuits around them. I think you'll see more amateurs using SCF chips and coming up with new applications for them. ■

Your Own Optoelectronic Anemometer

Light control and car-top calibration make this project cheap to build, easy to align, and extraordinarily accurate.

Charles E. Heisler K3VDB
115 Dixie Drive
Red Lion PA 17356

In my January, 1983, *73* article, the question was, "Can you really see which way the wind is blowing with optoelectronics?" Now, I ask, can you really see *how fast* the wind is blowing?

The answer to both questions is, of course, yes. We will use the GE H13A1/H21A1 interrupter module to tell us wind velocity—how fast the wind is blowing.

Perhaps I should reiterate at this time that the GE number for the H13A1 interrupter module has been changed from H13A1 to H21A1. The modules are interchangeable. So from here on, I will refer to it as the H21A1.

General Circuit Description

This circuit uses very few electronic components. A good portion of the work involved in building the anemometer head is the mechanical end of it. But more about that later. The electronic components consist of an H21A1 and a 2N3904 transistor line driver up in the head of the anemometer. Down in the shack there is an LED that blinks when the wind is blowing (I am not quite sure why I put that in there—I guess I just like whistles, lights, and bells). There are twelve in-

verter gates in the two DIP packages, a few resistors and capacitors, a 3.6-volt power supply, and a 1-milliamp meter. Perhaps I should mention at this time that the meter and your calibration are the only two things that would limit the accuracy of the electronic circuit. The electronics are extremely linear, so it is important that you use a good meter, one with which you can redo the scale as we did—it's not hard. More on that later, too.

The MC789P or ECG9989 RTL inverters are part of an old family of ICs, but they are still readily available at an inexpensive $3.00 price. The most important reason we like this circuit is that it works without a hitch.

The trend toward digital readouts is usually an improvement over the old analog meter, but there are always exceptions to the rule and, in my opinion, wind speed is one of them. Unless, of course, you need a digital number to be used in an automated calculation, the old analog readout is a more comprehensive representation of what the wind is doing.

About the Circuit

From the schematic and the test-point waveforms in Fig. 2, the theory of the circuit will become apparent. A three-wire shielded cable is required to connect the anemometer head, up on the tower, to the readout in the shack. From there on it's just ones and zeros. Well, almost. The first entire IC package (6 gates) is used for shaping and compensating the input pulses. The second chip uses an RC network to generate a low for the exact period of time it takes to make the meter read correctly.

Switching-in the .47 μF capacitor affords you a full scale of 30 mph (a good scale for normal operation); during a storm, flipping the switch will give you 90 mph full scale. The 2000-μF capacitor across the output tailors the meter to a nice,

Photo C. A view of the bottom of the top bearing and the gasket that will seal the weather cover.

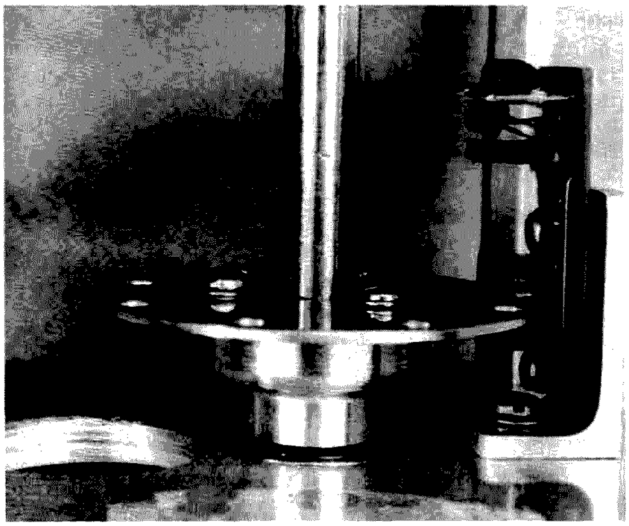

Photo D. The disk interrupter with its 8 holes running through the H211 interrupter module.

smooth, responsive movement. The 3.6-volt power supply is a snap; we used one of the adjustable three-terminal regulators from Radio Shack (number LM317T). The 150-Ohm pot allows ease of adjusting the output to 3.6 volts.

The data in Table 1 concerning mph, mA, pps, and rpm is supplied for reference only. Your anemometer may not perform exactly as mine did, but this data will give you a starting point.

If you have a signal or function generator with a 1.5- to 3-volt range and you can adjust its frequency from 7 Hz to 130 Hz with reasonable accuracy, you should be able to duplicate these readings by substituting your generator for the input from the anemometer head. I have gone one step further and used the generator to drive the H21A1 emitter directly by removing the 100-Ohm dropping resistor from the 3.6-V positive bus and connecting the generator to the free end of the resistor and to the negative bus. Of course, in this case, the anemometer head will remain connected to the readout board.

As seen in the photos, the electronics in the head and at the readout are mounted on PC board, Radio Shack #276-170. But I cannot recommend this board. For my purposes, the board worked out fine mechanically. However, when I wanted to solder to it, solder would not flow as I thought it should (even after cleaning), so additional flux was used resulting in nice wet-looking joints but a lot of flux residue. The board was tested and worked fine. By the way, the circuit was debugged and tested on a push-on breadboard before assembly on the Radio Shack board.

The board was then washed in a commercially available flux remover, and that's when my trouble started. After a few hours of "What the h— happened to this thing?" and "I can't believe what the scope is saying," I finally found I had contamination bridges all over the board. I had never used fiber PC board before and never will again. I had used the flux and flux remover together lots of times with no trace of trouble, but always on glass board. I finally washed the whole thing in detergent and water after trying some other solvents to no avail.

After drying and retesting, I gave the solder side of the board a coat of clear Krylon™. It has been doing fine ever since. The moral to the story is to use a good glass epoxy board.

There is only one other electronic component that bears mentioning, that being the GE MOV #V18ZA1 metal oxide varistor, located in the anemometer head. It plays no part in making the circuit work; its job is to limit the voltage on the 3.6-V bus during a lightning strike or other power-line spike. They have proven to me to be very effective in their job of over-voltage spike protection. If these units are sized correctly for the job, they will conduct during a spike and then restore to normal, over and over again. For their low price they sure can save you a bundle of trouble. So a word to the wise is sufficient: If you are not familiar with the MOV line, you may needlessly be jeopardizing some of those priceless gems in your shack.

The Mechanics

The model pictured in Photo A has 4″ cups. They are bigger than they would have to be for just a wind-velocity meter. These cups were fabricated from 4″ aluminum funnels. I cut the snouts off the ends of the funnels and bent very thin aluminum sheet metal into the shape of a cone to close the holes. Then I secured it to the funnels with aluminum pop rivets. I would suggest using aluminum soup ladles, approximately the two-inch size, for your cups. The rods are ¼″ aluminum, threaded on one end to secure the cups, and they're approximately 2.25 times the diameter of the cups in length. The hub that mounts the rod to the shaft was machined from a solid piece of aluminum round stock 2″ × ¾″ thick. Holes were drilled and tapped for set screws to secure the rods and shaft. If soup ladles were used I am sure some bolting or clamping arrangement could be devised to secure the ladle handles to the shaft. This would eliminate the need for a machined hub, if the machine work is a problem. I would also recommend using a ⅜″ shaft instead of a ¼″ shaft.

Photo B is a view of the anemometer with the cup assembly removed to get a better look at the top bearing seal and the side mounting surface. The top bearing seal is exactly as described in the previous article ex-

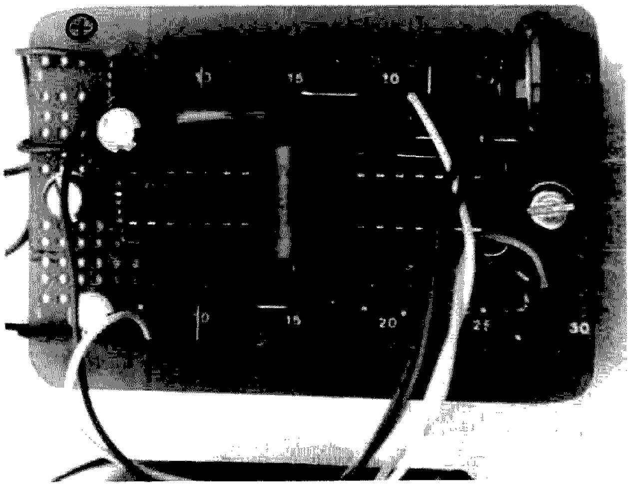

Photo E. The circuit board that drives the readout meter. Note test points.

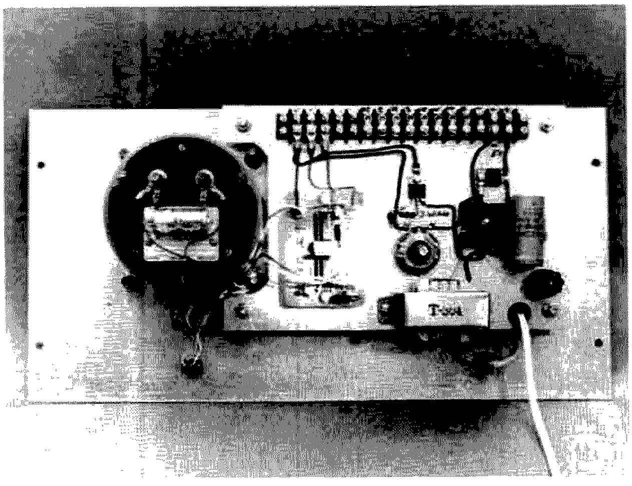

Photo F. Rear of readout panel.

cept it is epoxied to the shaft instead of clamped with a set screw. The mounting surface would depend on what you are going to mount it on. We mounted the wind-velocity and directions heads on a piece of 2" × 2" box aluminum approximately 5' long and bolted it to the tower. There will be some wind load so whatever you mount it on must be good and stiff.

Photo C is a view looking up under the top plate to show that the bearings in this unit were pressed into the ¼" top plate and bottom plate rather than using bearing blocks as described for the wind-direction model. I prefer the bearing block method because of ease of precision alignment. Also shown in Photo C is the cork gasket used for sealing the five-sided weather cover.

Photo D is a look at the disc interrupter running through the H21A1 with its associated electronic components such as the 2N3904 line driver, the V18ZA1 MOV, etc. The disk interrupter is nothing more than a 2½"-round by ⅛"-thick aluminum disc with eight evenly spaced ¼" holes in it. It is secured to the shaft by a machined collar. It also serves as the bottom shaft stop, which rides on top of the bottom bearing. Collars such as those pictured in Photo C can be purchased for approximately $1.00 at any machinery house, and the interrupter disc could be epoxied to it instead of a machined collar.

The PC board is mounted on a piece of aluminum angle with insulating standoff washers (such as are used in mounting transistors to heat sinks). The hole in the bottom plate that the angle mounting screw goes through is oversized to facilitate alignment. The same method used in the wind-direction indicator for getting wires off the board and down to the shack is used here. There are two male pins near the top of the board and one female pin covered with shrink tubing below. Another method would be to run the three wires of the board to a barrier strip as pictured in Photo F, but with only three lugs of course.

Photo E is the electronics board at the readout. Layout of this board is not critical. (Where have I heard that before?) The vertical trimpot at the right-hand corner is the calibration pot. It's the only electronic adjustment in the whole circuit except for the power-supply voltage.

Photo F is a view of the back of the readout panel. This panel as seen in Photo G is used for wind direction and velocity with some spare room for future generator control. On the left is the velocity meter with the 2000-µF capacitor across its terminals. Under the meter are the range switch and blinking LED. On top is the barrier strip on which all the wires terminate that go to the two heads up on the tower. Next are the electronics board as pictured in Photo E, the 3.6-V regulator and adjusting pot, and the 5-V regulator for the wind direction electronics. Below are the rectifier bridge, filter capacitor, power transformer, line fuse, and on-off switch.

Photo G is of course a front view of the readout panel. Perhaps now is as good a time as any to talk about the meter scale. As I mentioned before, this scale was hand calibrated, reincremented, and numbered. For those of you who have never tried that sort of thing, let me tell you, it's not as hard as you might think. However, you must start with a one-milliamp meter that you can separate without destroying. We will get into calibration shortly.

Take the meter apart and very carefully remove the face. You will find the bigger and better meters are easier to work with. Then spray the face with a flat white spray can until all traces of the old markings are no longer visible except 0 and full scale. When dry, give it a coat or two of clear Krylon. Now new increments and numbers can be put back on with comparative ease. Use a fine felt-tip black indelible pen, such as used to mark clothing, for the increments. They must all point to the pointer shaft. The meter in Photo G has a 4" face and I used ¼" vinyl stick-on numbers. You can also use roll-on numbers but in my opinion, they are harder to work with. The pen and the numbers can be purchased at any stationery store.

Calibration

I am sorry to say I have no sure-fire method for you to follow. But I can tell you how I set mine, and it duplicates the reading of a commercial unit not far away. After looking high and low for a calibrated wind tunnel with an aperture big enough to get this thing in, I finally gave up and decided I must come up with some other method. The only way I could think of to calibrate

the meter was with my Jeep. It has a roof carrier on top so it would be no problem to mount the anemometer head on it and just calibrate my new gadget by driving down the road using the speedometer for my reference.

But how accurate is the speedometer? After beating the bush a little more, we found an automotive shop that was set up to certify auto speedometers for police departments, and after telling the fellow what I wanted, he agreed to test my speedometer for a nominal fee. He would make no corrections but would give me a graph showing what my speedometer indicated and what the true speed was. Well, that sounded good to me. It turned out that my speedometer was flat up to 70 mph. I am told it is not unusual for an auto speedometer to be a fairly accurate device if the car has the original size tires and they are not worn too badly.

I got everything ready, brought a few pieces of wood to help mount the head to the roof carrier, and installed the weather seal cover, etc. As soon as a nice zero wind day came along, we would be ready to go. The day finally came, with my son Mike at the wheel and me in the back seat with all the goodies: a counter, DVM, the readout panel, and a 12-volt battery which, by the way, is how we powered the input of the 3.6-volt regulator during our mobile test. After hitting the open road, calibration went very well. I had already established, with the function generator described before, that the electronics were sound. But we had some apprehension about the cups being nonlinear at the very low end and the very high end. But even with the over-sized cups used in this model, linearity did not display itself as a problem. The calibration pot was set at exactly 30 miles per hour to indicate 1 milliamp on the meter (with the range switch set to the zero- to thirty-miles-per-hour position). At this speed, the counter indicated 43.0 pulses per second. With a few more tests and a little help from the calculator, we calculated how many pps we should get every five miles an hour from 5 mph to as fast as we could go.

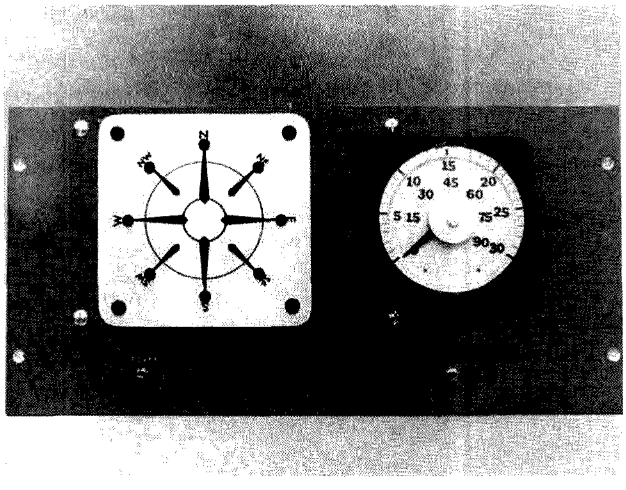

Photo G. Face of readout panel.

Surprisingly, everything held out very well. However, we still had some doubts about the top end of the 0-90-mph range, so I said to Mike, "Let's make one more high-speed run and then head for home." Well, let me tell you everything was looking good. We came up through 30 mph, 45 mph, and 60 mph, and I was thinking to myself that if we could only hold 75 mph for a few miles I would be satisfied that we had made a valid test. I heard Mike say "uh oh," simultaneous with what I recognized immediately as the wail of an electronic arm-of-the-law-type siren.

I think the cups on top were still turning as that big dude walked over to the Jeep. He did not want to believe that thing on top was not some new device designed to foul up his radar. Nor did he stop writing when I mentioned that maybe Wayne Green would hear about this. So, like I said before, I wish I could tell you a better way to calibrate this thing.

The test data in Table 1 was obtained from the aforementioned test, so it was possible now to go back to the bench and use the function generator to reincrement the meter.

If you don't have a generator, you can mark the face of the meter at the 5-, 10-, 15-, 20-, 25-, and 30-mph points with a pencil while you are doing your calibration run and then ink them in later.

After reincrementing and numbering the face, it was given an additional coat of clear Krylon, reassembled, and retested. The whole system has worked fine ever since.

May I take this opportunity to thank my wife, Ann, for her help and support while getting this article together. And, of course, my son Mike who got the ticket. ■

Rampant RTTY

Create the ultimate mailbox! K0WVN describes a system that operates from 45 to 1200 baud with dual shifts—automatically!

A ROM-116 RTTY mailbox system is a good tool for local amateurs to keep in touch with each other on VHF and UHF frequencies. It can also be used in disaster-type operations as temporary storage for messages.

I witnessed a great need for this sort of system when I happened to be listening to a bunch of VHF phone traffic after a small tornado hit a portion of Topeka. There was so much delay caused by hand copying and repeating of information that I felt sorry for the operators. A RTTY mailbox system would have been the answer to their communication problem; just a plain RTTY system with a printer would have done the trick.

Later, after the operation was completed, the local club did invest in RTTY communications for both the mobile unit and the base station. I am sure that the system will speed up this sort of traffic handling and improve accuracy. When the traffic is coming in from all directions, it is nice for a RTTY system to remember what was said and be able to print it out when you want it.

Flesher Corporation is now the sole distributor of the ROM-116 and is now responsible for its future. This interface has proven to be one of the most dependable systems ever made to interface with the Radio Shack TRS-80 (Models I, III, and 4). The author of the ROM-116 software, Craig Larsen WA7HTN, and his partner, Gary Martin W7XT, spent a great deal of time creating a system that would satisfy even the most picky operator (such as myself).

Crown Microproducts (located in Marysville WA) was made up of these two dedicated hams, and between the two of them, they created their primary product, the ROM-116. I know that Craig had spent a great deal of time on the standard operating software and was in no mood to tackle another project. His time spent creating the software probably did not return him fifty cents an hour, which sours many a programmer from creating hobby software to begin with.

After so many hours of Craig's time in writing the standard RTTY/CW software, it was a struggle for the ROM-116 users to talk him into writing another

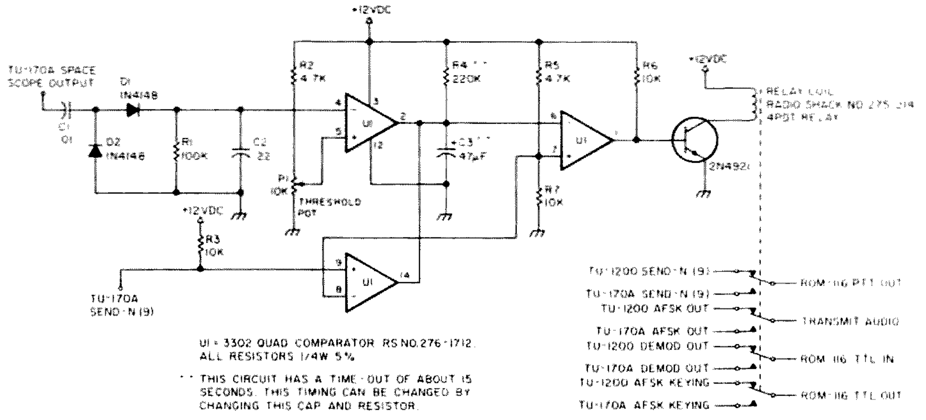

Fig. 1. The circuit and the relay connections. Caution: Do not use the TU-1200's 12-V-dc power supply to supply the circuit or the relay. The TU-1200 will not handle any supply drain outside of the unit.

software creation. It takes time, patience, total concentration, and determination. You can imagine; both of these fellas already had a full-time job, and total concentration can be hard to achieve in a family atmosphere.

After several prototype mailbox programs, Craig finally settled on version 1.4.2 MBO for the Model I and 3.4.2 MBO for Models III and 4. I will briefly touch on a couple of features that the ROM-116 has to offer, at least the ones we will be working with on the additional circuitry.

The ROM-116 mailbox-system communications-rate feature is like none other I have seen. It has ability to receive a remote command over the airways to change the baud rate from 45.5 to 1200 baud. This is one of the few (if not the only) systems that has the ability to run at this fast of a baud rate and still maintain a split-screen format. The control operator has to initialize a baud rate agreeable to everyone on the system, and this initialized baud rate will set a default. If a mailbox user accidentally sets a speed that he is unable to communicate with, the system will delay and default back to the speed set by the control operator. This is only one of many fine features the system has to offer, and it would take another article just to explain the remaining features of the ROM-116 mailbox software.

I had a problem with the hams in this area when I tried a system that had to have an "open command" before you could ask the system for your mail (which was another command on top of that). After you started the mailbox system sending your mail, you had to remain in the shack to give it an "exit command." The users of this mailbox system started dying off, discouraged with the procedure required in order to get the mail. Most of the users wanted a system that would allow them to go into the shack, give a read command for their mailbox, and walk off—having the messages print out without having to wait to close the mailbox.

The ROM-116 mailbox software was the answer to this problem, and everyone was happy with the elimination of a lot of "Howdy," "Exit," and all that sort of chit-chat from the computer on the other end. This is called user friendly according to some, but our group calls it time-consuming nonsense. For some reason, there is a large number of operators that like mailbox software programs that talk a lot to the users of the system. Our group here could care less about chatting to the computer; it seems to insult their intelligence.

It is not the purpose of the system to carry on a conversation with a computer controlling the mailbox system.

Our system was very simple—nothing fancy or expensive to maintain. The rig consisted of an old 1950s-vintage General Electric VHF transceiver that had a Flesher Corporation HF-144 on the receiver to give us about a 30-dB gain for those weak signals. It could transmit 50 Watts all day long. This rig had held my house down during high winds for many years, and it took the better part of our backs to remove it from my shack. After we healed from the hauling of the transceiver, we acquired a Radio Shack TRS-80 Model I with 48K of memory (and one disk drive from Andy Anderson KØNL). A single-density disk will not hold very much data for a mailbox system, so I purchased a double-density controller board and installed it into the expansion interface of the TRS-80. I had three ROM-116 interfaces (for some unknown reason) and I donated one for this interesting project, along with the antenna. Jerry Flesher KØTNC donated the location and a TU-170A. It was all interfaced together, and the final tuning was done by Gene Godsey KØBXJ.

Well, everything seemed to be running smoothly. The ROM-116 and the Flesher TU-170A ran flawlessly for over a year. Then, Flesher Corporation came out with the TU-1200 terminal unit, capable of running at any rate from 45.5 to 1200 baud. Here is a terminal unit that would do both Baudot and ASCII and could be run at the full output rate of the ROM-116 system. Up until this point, we had been limited to the 300-baud maximum of the TU-170A.

The TU-1200 is a 1000-Hz-shift terminal unit using 1200-Hz and 2200-Hz tones (Bell 202 compatible). The TU-170A had been running 170-Hz-shift (2125-Hz and 2295-Hz) tones.

Okay, we could now get our speed up, but there was one minor problem of what to do about the people still wanting to use the 170-Hz shift. I wanted to have both on the same system. It was hardly worth two identical systems just for faster baud rates.

So, the problem was to find a way of using both the TU-170A and the TU-1200 on the same system without sacrificing anything we already had. After trying several circuits, a workable solution to the problem was found. By detecting the space signal (2295 Hz) from the scope output of the TU-170A, we were able to make the system work perfectly normally for either terminal unit.

As shown in Fig. 1, the space scope output of the TU-170A is fed into the circuit through C1 and D1 to pin 4 on U1. A threshold pot (P1) is used to set the sensitivity of the input. Time-out delay is set with the combination of R4 and C3, and with the values shown, the delay will be about 15 seconds. When a space signal is detected from the TU-170A, U1 will trigger Q1 and then pull in the relay, connecting all the necessary I/O to the TU-170A. When the circuit remains inactive for the set time (determined by R4 and C3), the relay will then release and reconnect the I/O to the TU-1200. The TU-170A SEND-N (pin 9) connects to the circuit board at pin 9 of U1 and also connects to one of the relay contacts (normally open) of the relay. When the 170-Hz shift is detected and the relay is pulled in, the PTT of the ROM-116 will keep the input at U1 pin 6 constant and prevent the circuit timer from timing out and dropping the relay during transmission.

A 12-V-dc DPDT relay with 5-Amp contacts is installed inside the ROM-116 and is used to make contact with external PTT requirements. The relay will key a common to the TUs and to the transmitter PTT input. This was a must on our setup since the PTT relay inside of the transmitter is powered with about 30 volts ac, and solid-state devices do not mix with ac too well. Some VHF and UHF rigs may pull a lot of current on the PTT inputs; the relay would be the answer to this situation, too.

Adjusting the threshold potentiometer (P1) of the detector circuit can be done by connecting a 2200-Hz tone oscillator to the audio input of the TU-170A and adjusting P1 so that the 2200-Hz tone will not activate the relay. Touching up on this adjustment may be required in actual operation at a later time. Power for the circuit and the relay can be obtained from the TU-170A's power supply. I built the circuit up on a piece of hobby perfboard which can be bought at Radio Shack (along with most of the other components).

The TU-1200 is not just for the group that has 1200-

baud capability, it is for anyone that wants to use the system from 45.5 baud to 1200 baud. If anyone wishes to access the mailbox system with a 170-Hz terminal unit, it is no problem at all. Using 1200 baud sounds like a buzz saw to those not familiar with the sound, and it is impossible to read as it is being displayed on the screen. I can now get a long picture or bulletin from the system, save it to memory, and print it out later, or save it to disk. What used to take forever (receiving text at 60 wpm (45.5 baud)), now takes only a matter of seconds.

This circuit seems to be very quick when switching, so nothing seems to be cut out. The ROM-116 RTTY operating software has a diddle feature that can be set to however many diddles you desire. I set mine for 10 diddles, and this seems to do fine for even the 1200-baud operation. There is a delay due to the PTT circuit in both the mailbox system and my system. So, by the time my transmitter drops out and is ready to receive, I may have missed part of a word. However, I do not see that this is a big problem. A change can be made to allow for the delay in the mechanical relays in the software.

We all got the word about the FCC not requiring CW identification every ten minutes while on RTTY. Now all we have to do is give identification in RTTY. Well, the following will tell you what to change in order to do this with your ROM-116 mailbox system.

The TRS-80 Models III and 4 can use the patch utility to make the following changes. The Model I will have to use a utility such as NEWDOS's SUPERZAP. The changes are as follows:

Model I, Ver 1.4.2 MBO
Address: 6D61H
Find: D5 3A A0 83 21
Change to: D5 C3 88 6D 21

Models III and 4, Ver 3.4.2. MBO
Address: 6DA9H
Find: 3A F5 83
Change to: C3 CF 6D

The exact patch format is: PATCH MBORTTY/CMD:0 (ADD=6DA9,FIND=3AF583,CHG=C3CF6D)

While this fixes the program so it will not send the CW identification, it also eliminates the only ID it has. So, the following patches will identify in RTTY whatever you have stored in buffer 6, such as "DE KØWVN MAILBOX SYSTEM TOPEKA." Here are the necessary patches:

Model I, Ver 1.4.2 MBO
Address: 57DBH
Find: 0A 00 C9 D7 0A 0A
Change to: 0A 00 C9 D7 0A B6

Models III and 4, Ver 3.4.2. MBO
Address: 57A4H
Find: C9 D7 0A 0A 00
Change to: C9 D7 0A B6 00

The exact patch format is: PATCH MBORTTY/CMD:0 (ADD=57A7,FIND=0A,CHG=B6)

Model I, 1.4.2 MBO: Addresses 57CF, 635D, 6379, 63B4, 63ED, 6418, 6454, 64AA, and 64F4; Find 4E; Change to B6.

Models III and 4, 3.4.2 MBO: Addresses 5799, 63A4, 63C0, 63FB, 6434, 645F, 649B, 64F1, and 653B; Find 4E; Change to B6.

After these changes are made, whatever you decide to enter into buffer 6 to be printed as an identification, be sure to add a carriage return before entering anything else in the buffer.

This should give you a super sytem, one that will operate trouble-free for a long time to come. Those of you using a different terminal unit can probably interface it in the same manner as the TU-170A with the TU-1200. In any case, I hope you have fun using the system and the faster baud rates. ■

Decode Soviet Space Messages

As you read this, mysterious signals are being beamed into your shack. What do they mean? Where are they coming from? Use WDØBCI's satellite-telemetry reading program to uncover the facts.

You hear it on the high end of 10 meters whenever the RS satellites pass over: *RS5 KOO DOO OOO GOO UOO WOO*—the heartbeat of the satellite, the telemetry beacon. It provides a constant stream of data about the health of the spacecraft, but what does it all mean? Is there a way to figure it out? Take heart, because I am about to describe what the telemetry means, the hard way to decode it, and a much simpler way to decode it using a computer (you do have a computer, don't you?).

The telemetry provided by the RS series of satellites contains a wealth of information about the operating parameters of the spacecraft. It will tell you everything from the power output of the transponder to the ambient temperature. This information gives you an overall view of the health of the system. It can also tell you such things as how much time the satellite is spending in sunlight, or the moment when the satellite passes into or out of Earth's shadow.

So why bother to take an interest in this data? For one thing, the telemetry tells you if the transponder is turned on. You can't make contacts through the bird if it's not listening. Also, you can tell when the satellite is on the decline and about to fail. Besides, it can become

Frame	Chan.	Parameter	Unit of measure	Decoding formula
( )/E	K	Output power of transponder	mW	$(N^2)/5$
	D	Voltage of power source	V	0.2N
	O	Load current	mA	20 (100 – N)
	G	Telemetry test	—	None
	U	Hermetically-sealed container pressure	—	None
	S	Temp. of stabilizing unit	°C	N
	W	Temp. of transmitter radiator	°C	N
I/S	K	Output power of transponder	mW	$(N^2)/5$
	D	Zero-setting of telemetry mV meter	—	N
	O	Output power of beacon	mW	$(N^2)/5$
	G	Repeater sensitivity control	dB	N
	U	S-meter for 1st service receiver	S	0.1 (N – 10)
	S	S-meter for robot receiver	S	0.1 (N – 10)
	W	S-meter for 2nd service receiver	S	0.1 (N – 10)
A/U	K	Output power of transponder	mW	$(N^2)/5$
	D	9-V voltage at transponder	V	0.1N
	O	7.5-V voltage at transponder	V	0.1N
	G	9-V voltage at 1st stabilizer	V	0.1N
	U	7.5-V voltage at 1st stabilizer	V	0.1N
	S	9-V voltage at 2nd stabilizer	V	0.1N
	W	7.5-V voltage at 2nd stabilizer	V	0.1N
M/W	K	Output power of transponder	mW	$(N^2)/5$
	D	Filling-out of robot log	QSO	N + 1
	O	Power of turned-on heaters	W	0.1N
	G	Power of robot transmitter	mW	20N
	U	Power of service-channel transmitter	mW	20N
	S	Sensitivity control for robot transmitter	dB	N
	W	Sensitivity control for service-channel transmitter	dB	N

Note: The first frame identifier indicates normal operation. The second frame identifier indicates that the satellite is being serviced.

Table 1. Formulas used to decode telemetry of RS-series satellites.

an interesting diversion from the ordinary operation through the satellite.

OK, so there's some interesting information there, but how do you get it from *K00 D00. . .?* Each character specifies a *channel* of telemetry. A channel is a single parameter such as the power output of the transponder. The telemetry channels are grouped into sets of seven which are known as *frames*. The frames are sent sequentially, and there are four possible frames in a full set of telemetry data. From one to four frames may be sent by the satellite, depending on how the ground-control stations have configured the satellite for the day's passes. Frame identifiers also change if the spacecraft is in service mode, when the satellite is being commanded by ground control, or if the transponder is switched off to give the bird a rest.

Now that you know how the telemetry is sent, how do you go about decoding it? There are two ways—manually and by computer. Manually decoding the telemetry has one advantage—it's cheap. If you want to decode it in this fashion, Table 1 provides you with the necessary formulas to do it yourself.

Decoding telemetry by hand is a relatively easy exercise, but it's kind of boring. Face it, you probably have better things to do than figure out values from equations. It's really kind of dry. Well, thanks to technology, you don't have to slave over those formulas. The computer revolution has set you free. If you have a programmable calculator, you can program the formulas into it and ease the pain somewhat. Of course, you still have to look at the tables to assign some meaning to the numbers you get from the formula. But if you have a computer, it can do the work for you and even label the results.

Listing 1 shows a program that accepts telemetry data and converts it to human-readable form. It is written in Basic for the IBM Personal Computer but can be readily converted to run on other machines by anyone who is familiar with Basic.

The program prompts you for the frame identifier of the telemetry data, and then for the numbers following the channel identifier. The computer will calculate the values for each of the telemetry channels and print the corresponding values, all nicely labeled, on the screen for your examination. This can be repeated for as many frames of telemetry as desired.

After studying the program, you might wonder why I didn't include any routines to provide hard copy of the results of the telemetry decoding. The simple fact is that on the IBM PC, these routines are not needed since there is a key on the machine that allows you to dump the contents of the display to the printer. If you are adapting this software to another system, it is a simple matter to write the necessary routines to provide hard copy, or to replace appropriate PRINT statements with LPRINT (or whatever your particular system requires).

Now that you can understand this data, what can you do with it? For starters, try graphing load current on a pass-by-pass basis for sev-

eral passes. Look for a long-term trend. I have suggested this exercise because load current varies with such things as transponder load and the input power of each user into the satellite. It is probably the most variable of the telemetry data and usually shows changes more readily than any of the other parameters.

Voltage at the power source is also an interesting parameter to watch. It can indicate a satellite-damaging condition such as battery overcharge (usually fatal if prolonged or excessive). If the voltage suddenly changes, it is a good bet that the satellite has passed from daylight into darkness or vice versa. Most of the parameters are worth watching for long-term changes (monthly, seasonal, etc.). It can grow into an interesting pastime, much like keeping weather records. You can also pass the data along to AMSAT. They are always looking for telemetry information from amateur satellites.

Now that you are able to decode RS telemetry, try listening to the satellites on 29.500 and 29.450 MHz CW. You can do with it what you want, but in any case, have fun with the program and the data that you can obtain from it. You might even get more out of playing with the telemetry data than working people through the satellite! ■

The End of the Line

What's the point in sending power up the coax if it never reaches the antenna? These tips on connector installation and care will help maximize your station's signal.

Fred R. Cook WB5LBI
203 Spencer Drive
Lafayette LA 70506

As supervisor of automation and communications systems on offshore oil platforms, I have learned that the following methods and materials produce long-lasting results even in salt-spray conditions on motor vessels and oil platforms in the Gulf of Mexico. If care is not exercised initially, moisture and improperly soldered coaxial rf connections can yield undesirable operation of your antenna system.

Cable Preparation

Proper soldering of the RG-8 shield to the barrel of a PL-259 coax connector can be accomplished by tinning the braid as shown in Photo A. Tin the circumference of the braid in an area that will be under the solder holes in the connector. Tinning must extend well forward of the solder holes to allow knife cutoff of braid and center insulation as shown in Photo B. Cutting through the soldered portion of the braid requires a sharp knife and considerable pressure. Work around the cable using a rocking motion of the knife blade rather than slicing.

Place the knurled connector nut over the coax with the threaded portion facing toward the prepared end. Apply a small amount of silicone grease or petroleum jelly to the black outer insulation and thread the connector onto the coax. Make sure the tinned area is in full view in all four holes of the connector and that the center conductor is in view for soldering.

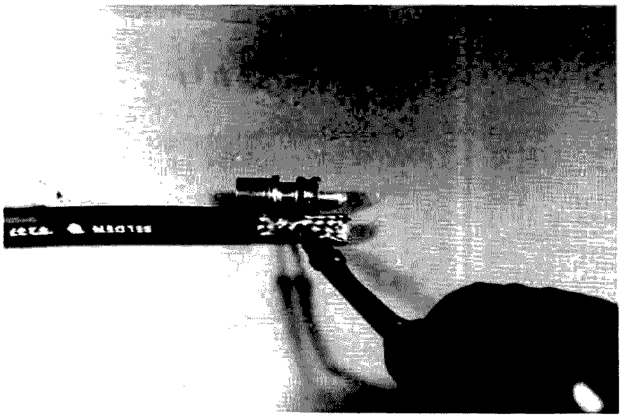

Photo A. Tin the braid in an area under the solder holes.

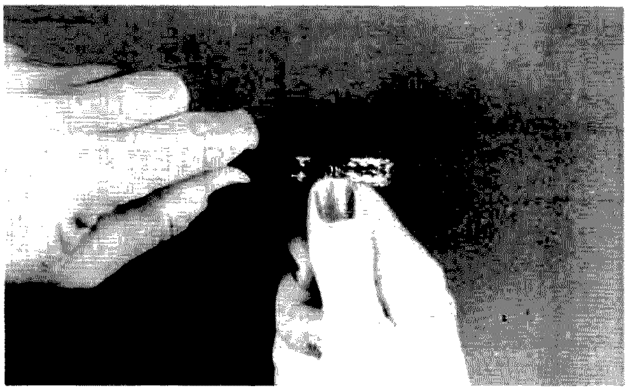

Photo B. Use a sharp knife to cut through soldered braid and insulation.

Photo C. Soldered connector with all holes filled. Use plenty of heat.

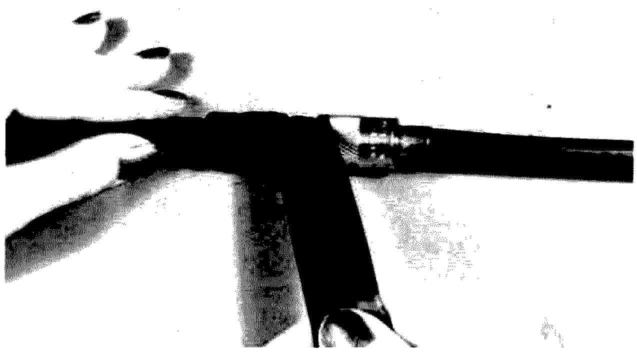

Photo D. Apply rubber tape with tension to conform to the irregular shape of connector.

Solder the Connector

Soldering must be done with enough heat to securely bond the coax shield to the connector. At least a 100-Watt soldering iron or gun is required to apply the necessary heat. Inadequate heat is responsible for most coax-connector problems.

Apply heat and then solder to each hole of the connector. Go from hole to hole around the connector with heat and solder. When the connector has absorbed enough heat, solder will freely flow into the holes and bond with the shield. It may take two or three passes in quick succession to achieve this. Next, solder the center conductor and allow to cool. The finished solder joints should be smooth and shiny—no solder beads or dull rough areas. See Photo C.

Now that your connectors are properly soldered, a check must be made to ensure that no shorts between the center conductor and shield have been created. A volt/ohmmeter, set on the 10k-Ohm range or higher and connected between center pin and body of the connector, should indicate infinite resistance if all is okay.

Protection Is a Must

Rf connectors used outside and exposed to the weather must be waterproofed to eliminate corrosion. Corroded connectors contribute to elevated swr and can radiate rf-causing TVI. A simple layer or two of vinyl electrical tape will *not* provide the necessary weather protection! The following method is used by radio technicians installing antenna systems in the Gulf of Mexico and can easily be applied by amateurs. I have used this method for eight years with no corrosion problems.

3-M Scotch® product numbers will be referred to, but other manufacturers' products are available to yield the same results.

Seal the Connector

The plug and receptacle portions of the connector must be joined firmly to provide a good electrical connection. The connector is now covered with a layer of Scotch No. 23 rubber splicing tape. Remove the protective backing and start wrapping 1/2" ahead of the connector on the coax. Stretch the tape at least twice its original length as you wrap, overlapping half the width of the tape, and continue the length of the connector. Be careful to fill voids and make the tape conform to the shape of the connector as in Photo D. This tape is both cohesive and adhesive and forms a solid covering.

A layer of Scotchkote® electrical coating is now applied liberally over the rubber tape for a sealer. See Photo E. This is a fast-drying liquid and imparts a waterproof seal. I have also used this type of sealant on bolted rf connections on antennas. It will coat the bolt and nut to retard corrosion and will allow removal of parts later. When the coating is almost tack free, start a layer of Scotch No.88 vinyl electrical tape on the coax just ahead of the rubber tape. The tape should be applied firmly with a slight amount of stretch. Continue down the connector, overlapping about half the tape width to the end, and then return in the opposite direction to the beginning. The last two wraps back at the beginning should be made with very little tension to avoid tape unwrap. Finally, one last coat of Scotchkote will seal the vinyl tape from moisture. Your finished product, in the case of a line splice, should look like Photo F.

This method should be used on all antenna connectors whether they be coaxial or coaxial cable terminated with screws and lugs. Also, many hams provide a splice connection at the tower to allow "fold-over." This splice should also be protected. ■

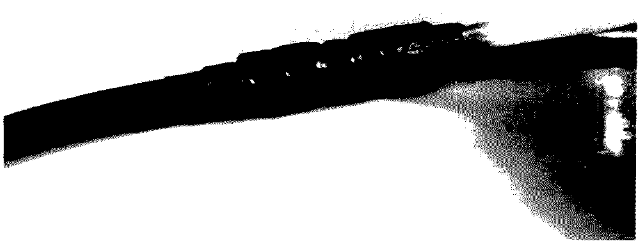

Photo E. Coat rubber tape with electrical sealer.

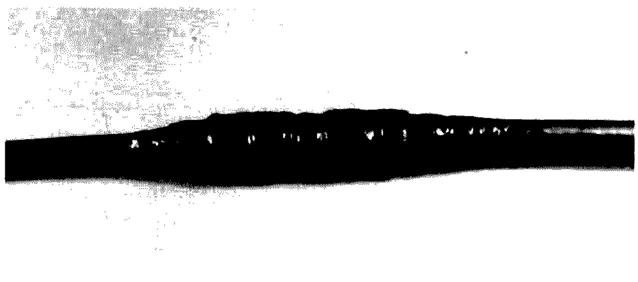

Photo F. Final covering of vinyl tape with outer coating of electrical sealer.

A Useful Present You Can Build

How about a high-tech holiday gift?

78900 Porto Velho, RO
Brazil

Learning new technology can be a painful experience and breaking into digital electronics on your own can be positively frustrating. That is why I decided to get some help in my attempt to update to digital electronics and enrolled in some classes at San Diego City College. (Yes, California does have more than surf and sun!) By the end of the first semester I had learned a little, so I decided to combine the final laboratory project with my need for a Christmas gift for my wife. Since wives don't always appreciate electronic gadgets, I felt I should come up with something she would consider practical . . . without attempting something that would be too difficult.

Happily, my wife likes to cook. And, conveniently, her old-fashioned kitchen timer had recently failed. The obvious solution was to build her a kitchen timer (eminently practical) using digital circuitry, as required for the lab project. I decided this timer would not need to display seconds, nor would it require greater than 60 minutes capacity. Its alarm should be audible for 50 feet in a normal house (whatever that is) and its display should be visible for 20 feet so it could be seen across a normal kitchen. Battery operation would be convenient, and I decided to lay out the controls for a left-handed user since the cook in my house is left-handed.

Theory

The timer is built around an up/down counter driving a seven-segment LED display, as shown in Fig. 1. The counter is set by clocking it up using push-button switches in the control section and is clocked down by a one-pulse-per-minute signal from the clock. The alarm, which is triggered by the counter's zero count, is modulated by signals from the clock so as to reduce current consumption yet achieve the required audibility. The control section includes an automatic power-disconnect circuit to prevent draining the batteries

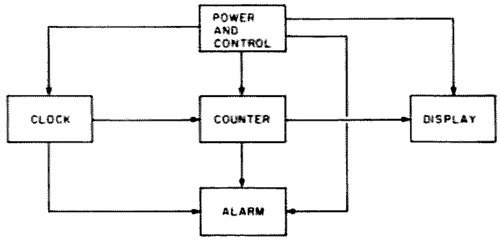

Fig. 1. Timer block diagram.

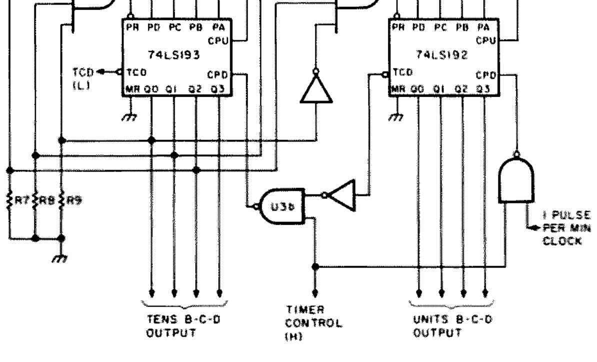

Fig. 2. Counter logic diagram.

by inadvertently allowing the alarm to sound excessively.

Circuit Description

The counter, shown in Fig. 2, utilizes two up/down binary counters in cascade. The units display requires a full decade, so a 74LS192 is suitable. The tens display requires only 0 through 6, so its counter is preset to zero by count 7 so that the timer cannot be set to more than 60 minutes. Using a 74LS193, whose count sequence includes 0 through 15, and wiring the preset gate, U4a, to force preset when the Q_0–Q_2 outputs are all high will cause preset on count 7 or count 15. The counter will then be forced to operate between 0 and 6 as it cannot be clocked up beyond 6 or down beyond 0.

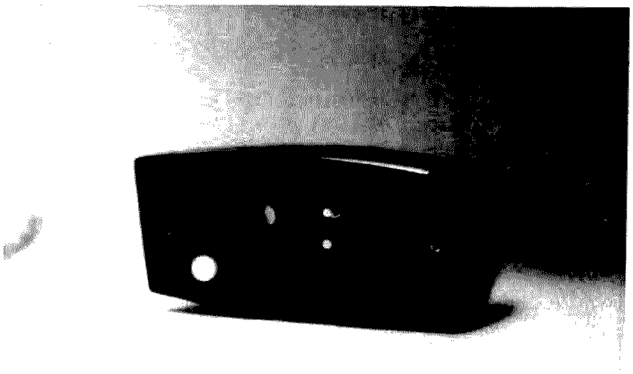
U4b is wired as a preset gate to force the units counter to zero when the timer is being set and the tens counter is at 6. This establishes 60 minutes, rather than 69, as the maximum timer capability. U4b is disabled in Timer mode when the Set control line goes low so as to allow the units counter to be clocked down normally. Otherwise the units counter would be locked at zero by the tens counter's 6, preventing the application of clock pulses to the tens counter, locking the timer at 60.

R7, R8, and R9 are pull-down resistors for the inputs of U4b. This was found to be necessary in order to prevent presetting on the 6 count due to "racing." Evidently, between count 5 (binary 0101) and count 6 (binary 0110), Q_0 was not going low before Q_1 went high, so the preset gate interpreted the 6 as a 7. The pull-down resistors cured the problem.

All clock lines must be held low when switching modes in order that their associated NAND gates be disabled. This will hold the clock inputs to the counters high during mode changes, thus preventing spurious clocking when switching modes.

The 74LS192/LS193 counters are designed to be cascaded by connecting the TC output of one directly to the CP input of the next. U3b, the Mode gate, inverts the TC_D signal before it reaches the CP_D input of the tens counter, so an inverter must be included in the signal path to restore the proper polarity. Without the inverter, the count is 50, 59, 58, etc.

Fig. 3 shows the waveforms of the counter in Timer mode with the units counter clocked by a symmetrical square wave whose period is 1 second. The Q outputs of the 74LS192/LS193 change states on the low-to-high clock transition. The TC_D output goes low with the low portion of the clock pulse when all its Q outputs are low. In Timer mode, counting down, the binary output of the units counter changes to 0000 with the rising edge of the 0 clock pulse. The falling edge of that pulse, 30 seconds later, causes the units TC_D to go low. 30 seconds later, the clock pulse again goes high, clocking the units counter to its 9 count and forcing the TC_D back to its high state. As the units TC_D goes high, it clocks the tens counter.



Digital kitchen timer in use.

S2, S3	Switch, PB, SPDT (momentary)	1.60	(Prices as of January, 1984)		

The BCD output from the counter section drives the seven-segment display decoders. Besides the 74LS48 decoders and the MAN-74 displays, the display section also includes a single LED which is driven by a 1-Hz pulse from the clock to serve as a Timer mode indicator.

The alarm section consists of a Radio Shack piezo sounder and appropriate gating. The Set control line, Q_0–Q_3 from the units counter, and Q_0–Q_2 from the tens counter must all be low in order to enable the alarm. When enabled, U6c holds the sounder's positive lead high. The sounder's negative lead is connected to a NAND gate/inverter combination that combines a 1-Hz square wave with a 10-Hz square wave. When these signals are both high, the negative lead is held high and the sounder is off. When either signal is low, the sounder will be energized. The result is a tone of about 5 kHz that is keyed at a 1-Hz rate and modulated at a 10-Hz rate.

The timer requires clock signals of 1 pulse per minute to drive the counter, 1 pulse per second the key the alarm, and 10 pulses per second to modulate the alarm. These signals are produced by a divider chain driven by an astable multivibrator, as shown in Fig. 4. The multivibrator output is a nonsymmetrical square wave whose high time, t_1, is 60 ms and whose low time, t_2, is 40 ms. The period, $t_1 + t_2$, is 100 ms and the frequency is thus 10 Hz. These times are determined by the following relationships: $t_1 = 0.693 (R_1 + R_2) C_1$; $t_2 = 0.693 \times R_2 \times C_1$. The 10-Hz signal from the multivibrator is used to modulate the alarm as well as serving as the input for the divider chain. The 1-Hz signal from the divide-by-ten stage is also applied to the alarm. When the Set control is high, in Set mode, the 74LS92 and the first 74LS90 will be disabled by the high applied to their R_0 inputs and the clock output will be held low. As mentioned previously, this is necessary to prevent spurious clocking when switching modes. Fig. 5 illustrates the clock-generator waveforms.

Power from four AA cells is applied to the circuit

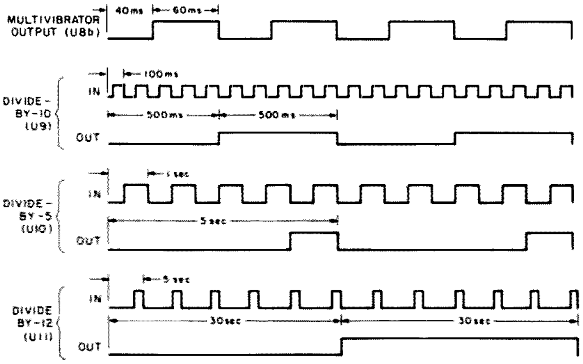

Fig. 5. Clock waveforms.

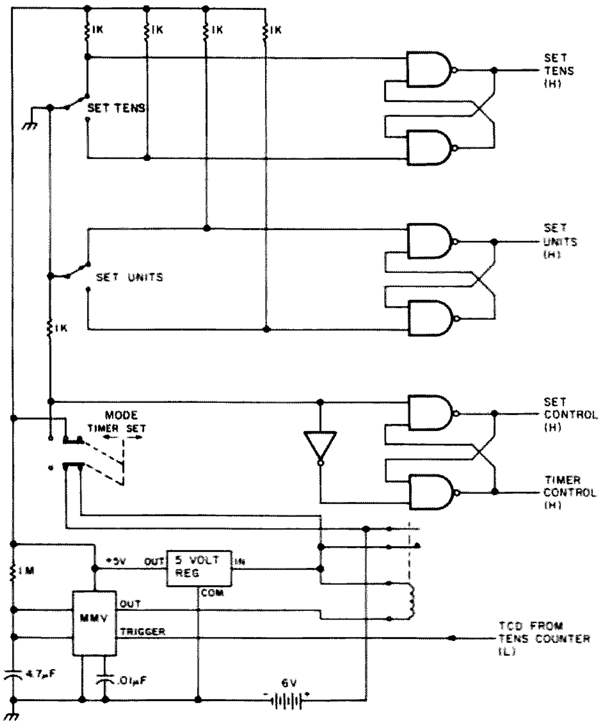

Fig. 6. Power and control logic diagram.

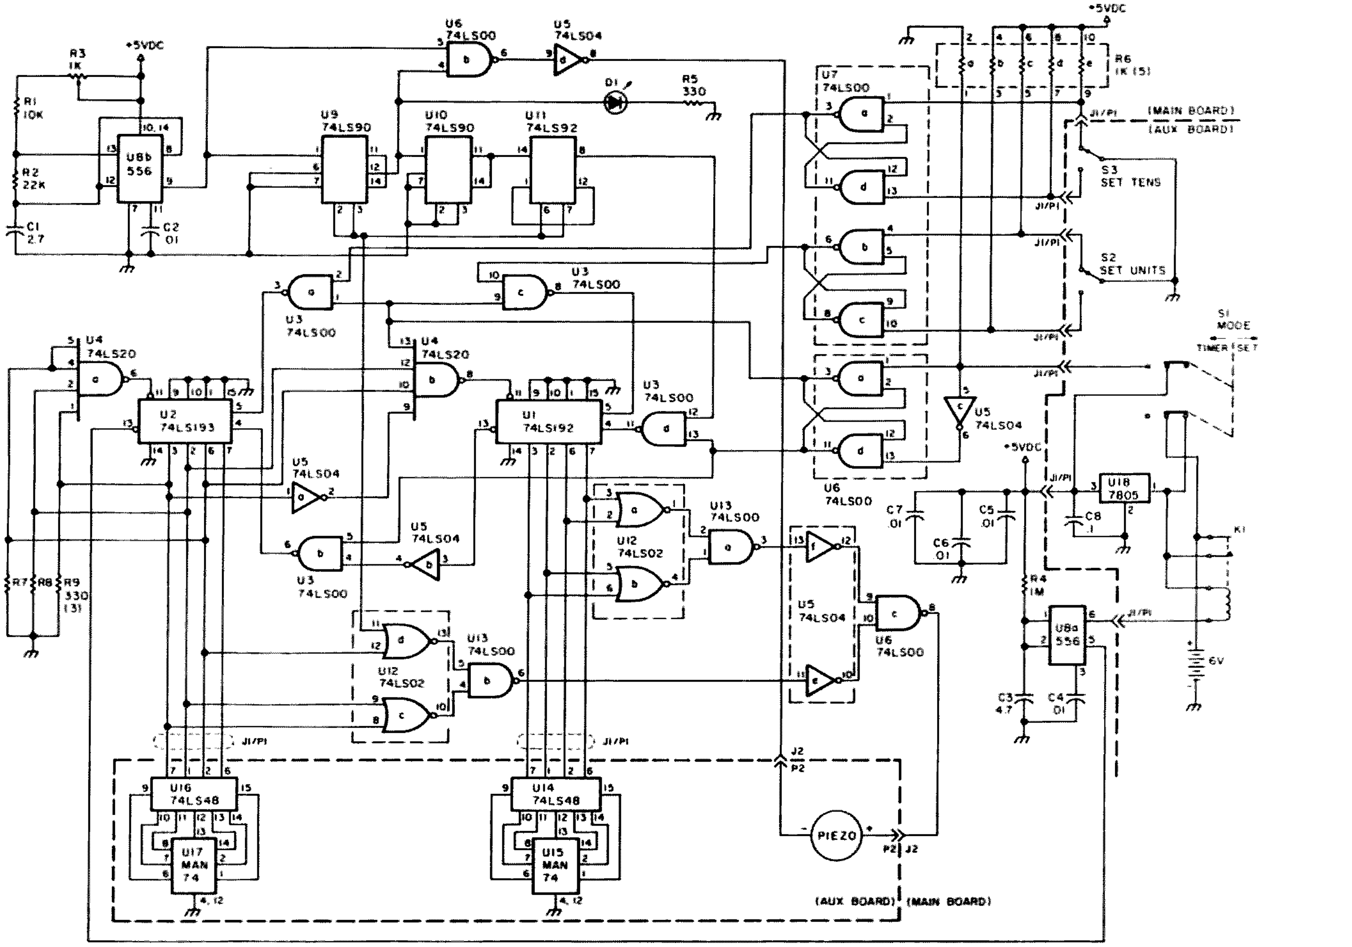

Fig. 7. Timer schematic diagram.

through normally-open relay contacts, as shown in Fig. 6. Placing the timer in Set mode applies power to the circuitry, providing a path to ground for the relay by energizing the monostable multivibrator. The relay, once energized, latches power to the circuitry even though the mode switch is moved to Timer. The positive transition of the last 0 pulse from the clock drives the counter to all zeros, triggering the alarm. 30 seconds later, the clock's 0 pulse goes low, causing the units TC_D to go low. When the units TC_D goes low, the tens TC_D is driven low. The low TC_D from the tens counter, which comes 30 seconds after the alarm sounds, triggers the monostable multivibrator. This drives the multivibrator output high, causing the relay to open, which provides the automatic shut-off feature after a 30-second alarm period. The period of the multivibrator, determined by the resistor/capacitor combination, is not critical as long as it is sufficient to allow the relay to open.

Push-button switches, debounced by NAND gates, are provided to permit setting the two counters individually. These are wired so as to hold the Set lines normally low to prevent spurious clocking when changing modes. Mode control is provided by an R-S flip-flop circuit controlled by contacts on the push-on/push-off mode switch. The mode-control signals, which are active high, are thus guaranteed to be complementary.

Construction

The timer is constructed in two units so as to fit a relatively compact enclosure, as indicated by the Main board/Aux. board divisions on the schematic diagram (Fig. 7). The main circuit board, shown in Fig. 8, includes the clock, the counters, the alarm gating, and the Timer indicator LED. The auxiliary circuit board, shown in Fig. 9, includes the control switches, the digital display, the piezo sounder, the battery pack, and the voltage regulator. These two boards are interconnected by means of a 16-conductor flat cable through J1/P1 and a 2-conductor cable through J2/P2. Though indicated together on the schematic, the decoupling capacitors (C5, C6, and C7) are spread out along the IC power bus.

I housed the timer in a black plastic case I chanced

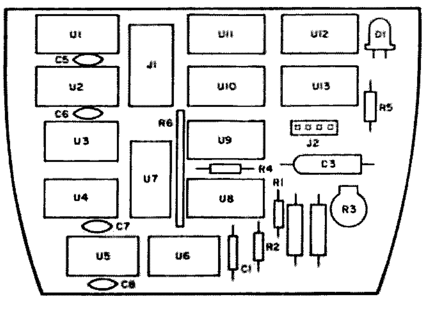

Fig. 8. Main circuit-board layout.

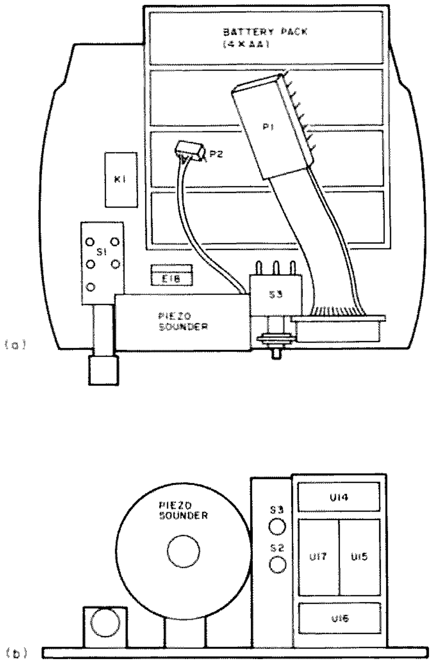

Fig. 9. Auxiliary circuit-board layout.

upon in a local surplus-electronics store, which is the reason for the strange shape of the circuit boards. The front panel is a red Plexiglas™ sheet through which the display is clearly visible. The controls have been arranged on the left side so that a left-handed cook can operate the timer without blocking the view of the display. The completed timer is shown in Fig. 10.

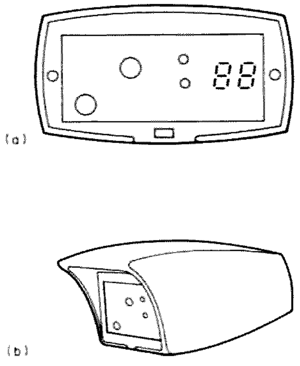

Fig. 10. Kitchen-timer views.

Conclusion

The timer has proven to be quite convenient to use. Pressing the mode switch latches the timer in the Set mode, allowing the user to clock the display up to the desired setting using the Set push-buttons. Setting the timer beyond its upper limit of 60 minutes returns it to zero, so setting errors can be corrected. Pressing the mode switch a second time releases it and places the timer in the Timer mode. A flashing LED indicates that the timer is functioning in this mode. The LED display is visible for a distance of 20 feet, except in very bright light. When the display reaches zero, an alarm sounds for 30 seconds, then the timer automatically turns off. The alarm is audible for a distance of 50 feet through several rooms in a house with carpeted floors.

Current drain from fresh batteries was measured as less than 150 mA, so battery operation is practical for occasional use. I have found it necessary, though, to install an ac adapter because my children like to play with Mom's kitchen timer—which suggests ideas for next Christmas! ■

Listing 1. VIC-20 Basic-language CW Banner program. The program initializes the screen and various memory pointers and nulls the new character-generator table before poking the machine-language program into memory. Execution is then transferred to the machine-language program.

Did you ever wonder just what your CW fist sounds like? I'm sure some of you have had a friend tape-record your signal from the air, but have you ever *seen* your fist? ("Why, of course," you answer. "Now do you want to *feel* my fist?")

Before you get hostile, please let me explain the little program in this article.

My CW Banner program is written for the unexpanded Commodore VIC-20 computer and will display on your television screen the dots and dashes received by your HF rig. As a bonus, it will do it in high-resolution graphics.

What you'll see when you run this program is a series of dots and dashes appearing on the right side of the screen and smoothly moving across the screen to the left side. As more elements appear on the right, older elements will disappear on the left. And that isn't all: The VIC will also beep the television audio in time with the dots and dashes.

This program can be a useful tool also for deaf hams who still want to work with dots and dashes and for displaying other TTL signals (with certain timing re-

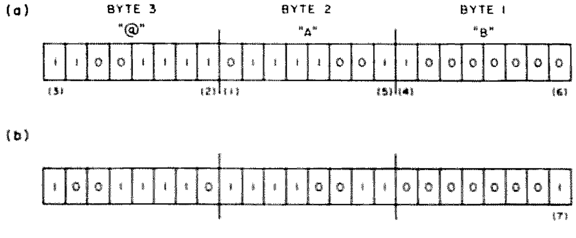

Fig 1. Example of how the first byte of each 8-byte character definition in the character generator is modified to roll dots and dashes to the left.

straints on the top end).

Fist still curled, you ask, "Well, how do we do all of that?"

I'm glad you asked.

Program Explained

To get the resolution we want from the VIC, we must change its character-generator pointer to point to RAM instead of ROM and then dynamically change what is in that RAM to define the dots and dashes we wish to see.

The ROM character-generator table contains eight bytes for each character that the VIC is capable of displaying. Each of the eight bytes defines one line of eight pixels in the 8 × 8 character grid. The table begins with the @ character and then continues with the alphabet, numerics, and graphic characters.

All we need to do is redefine one line in each of the first 22 characters in the RAM character generator (@ through U), setting a bit if a CW signal is present and resetting it if there is no signal.

Take a look at (a) in Fig. 1. This represents a simplified screen only three characters wide which I'll use to explain what the program does. Our three characters on the screen are @, A, and B. The program looks at the most significant bit (MSB) of byte 2. If it is low (1), then it resets the least significant bit (LSB) of byte 3 (2). If byte 2's MSB is high, then the LSB of byte 3 is set. In either case, the byte is then rotated one bit to the left and poked back into the character-generator table in RAM. The program then skips to the next byte, byte 1, and does the same thing (4 and 5). The POTY pin of the joystick port is then checked for a signal. If it is low (indicating a signal is present), the LSB of byte 1 is set, otherwise it is reset (6 and 7). Byte 1 is rotated left and poked.

I should remind you that the bytes we're messing with above are the first of the eight bytes that define each character. The other seven bytes were previously nulled by the Basic program and are not used. They remain transparent so that the only things visible are the dots and dashes that are defined by the first byte.

In Fig. 1, (b) shows the screen after the dots and dashes have been moved to the left by one pixel.

Listing 2. The object code produced by this program is contained within the DATA lines of the program in Listing 1. Mnemonics used in this listing are a modified form of those commonly used. (The "I" attached to some of the above mnemonics (LDXI, for example) means "immediate." ROLA means "rotate the contents of the accumulator left one bit," as opposed to ROLX, which does the same to the X register.)

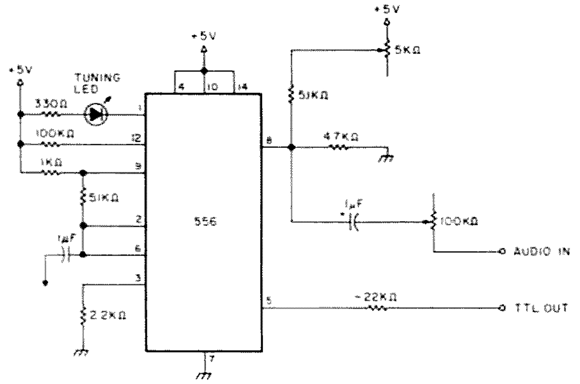

Fig. 2. Usable interface for converting your HF rig's audio to a TTL signal for the VIC-20. Do not omit the 22k resistor at the output.

In addition to redefining our 22 characters, the program will turn the audio on and off (see lines 560, 570, 640, and 650 in the assembly listing). This is an advantage if your rig's audio is muted or disappears because you have stuck a patch cord into the headset/external speaker jack.

One other desirable feature included is the ability to vary the speed of the characters moving across the screen. All you need to do is touch any of the keys on the keyboard to affect the speed. The letter keys are among the slowest, while RETURN and RUN/STOP are the fastest. The faster the code is coming from the rig, the faster you'll want the display to move; otherwise, the dots and dashes will be very short and hard to see. However, the slower the display speed, the more dots and dashes that can be displayed on the screen at one time.

The Basic program (Listing 1) does the following:

- In line 110, a part of RAM is reserved for the machine-language program. Line 170 turns up the sound. Then in line 150, twenty-two characters are printed across the screen. These are the characters which will be redefined as dots and dashes.
- Next, in line 170, the character-generator table is moved to RAM and line 190 fills the table with zeros.
- Last, lines 210-230 poke the machine-language program into memory and then transfer control to that program.

Hardware Required

The program as written may not be compatible with Kantronics' hardware. But changing the value of POTY in line 190 of the assembly listing to the input address that Kantronics uses and (if necessary) the logic used in the RITECHAR routine beginning at line 480 should do the trick.

For those of us who like to go our own way, Fig. 2 is the circuit I'm using to convert the rig's audio to the +5/0-volt signal that the VIC requires. Be sure to include the 22k-Ohm resistor in series (as shown) between this circuit and the VIC.

Kudos

I'd like to thank Skeeter N3HB for the original idea for the CW Banner project. His was written for a homebrew 6800 machine. I wrote the 6502 version for the VIC after gaining experience writing one for an 8085/TMS9918A home brew. ■

Homemade Defroster Shutoff

This simple gadget has nothing to do with amateur radio, but it's a neat little project anyway.

Is your car equipped with an electric rear-window defroster grid? Have you ever turned it on and forgotten about it until several days later? No? then don't bother reading any further.

Being somewhat absent-minded, this problem has been with me for years. I finally became motivated to build some type of automatic shut-off circuit when I purchased a new car. This car had a factory-installed defroster that was controlled by an on/off switch without a shut-off feature, and I felt my new "toy" deserved better than that. The original control scheme is shown in Fig. 1.

My old car was equipped with a fan that cleared the rear window by blowing the car interior's air at it. Marginal performance and a desire to mount a hi-fi speaker in its place had resulted in replacing the fan with a stick-on grid defroster. This after-market unit did not have a relay to control the defroster power; all the current flows directly through the switch.

Since I had decided to build a timer circuit, it seemed a good idea to install a similar design for this after-market, relay-less defroster.

As a first step, several design goals for the timer were developed. (1) The existing defroster was not to be altered, other than to cut wires. (2) There was to be no power consumption when the power-control switch was off. (3) The existing pilot light should indicate when power was applied to the defroster grid. (4) It should be possible to reset or turn off the defroster timer at any time. (5) The circuit should be able to cope with power-supply variations and noise.

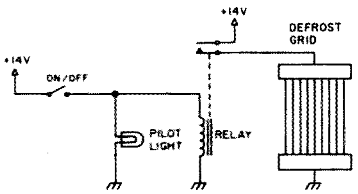

Fig. 1. The existing defroster circuit.

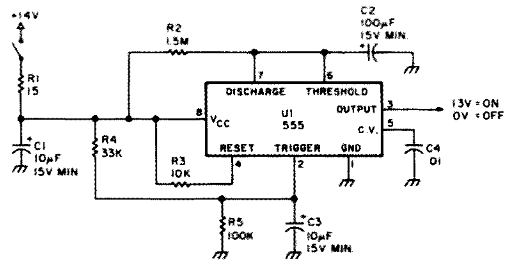

Fig. 2. Schematic of the timer circuit.

Circuit Description

Fig. 2 shows the circuit that evolved from the design goals. A 555 timer chip was chosen as the control element. R2 and C2 are the timing components. The values shown produce an on-time of approximately four minutes. This has proven to be adequate for most situations. Increasing the value of R2 will increase the on-time, and vice versa. The relationship between R2 and the on-time is roughly linear: doubling R2 doubles the on-time.

I have shown power-supply connections as going to +14 V. These connections are really to the positive side of the car's battery, and the voltage may not be exactly 14. The circuit will function over a wide range of supply voltages, however, so this is not a problem.

The 555 is triggered by a low voltage (less than one third the supply) at pin 2. C3 and R4 ensure a low voltage at pin 2 for a fraction of a second after power is applied. R5 guarantees a rapid discharge of C3 when power is removed, allowing the circuit to be reset and restarted quickly. R1 and C1 are a simple supply filter. The output of the 555 (pin 3) will be at zero volts when off (or when power is removed) and at about one volt less than the supply voltage when on.

There are at least three ways to configure the defroster drive circuit (R6, Q1, B1, K1). Figs. 3(a), 3(b), and 4 show the choices. With the circuit of Fig. 3(a), the exact timer output voltage does not make much difference; the key is to drive Q1 into saturation. When Q1 is saturated, its collector-to-emitter voltage is very small, so the voltage applied to the relay and indicator light is nearly the supply voltage. In addition, power dissipation in the transistor will be minimized.

If the circuit of Fig. 3(b) is used, Q1 will not be driven into saturation but will act like a large-signal emitter follower. Available drive for the relay will be about 2 volts less than the supply voltage due to the base-emitter drop across Q1, the drop in R6, and the limited maximum voltage at the 555 output. Power dissipation in Q1 will be increased be-

cause of increased collector-to-emitter voltage.

I recommend using the circuit of Fig. 3(a) when possible, but when the connections to the relay coil are difficult to access, it may be easier to use the configuration of Fig. 3(b).

Use Without a Relay

Due to the high current in most grid-type defrosters (10 Amperes or more), it is not advisable to drive the defroster directly with this circuit. If it is desired to eliminate the relay, the circuit shown in Fig. 4 may be employed. The added transistor, Q2, is to boost the current applied to the base of Q1 to ensure that it is saturated (minimum power dissipation). Q1 still may dissipate several Watts, so a heat sink should be used.

Construction

Layout and construction style are not critical. I chose to use a small piece of punched phenolic board for the timer and point-to-point wiring.

R2 and C2 are the only components with somewhat critical values. Most other components can be of whatever values exist in your junk box. Every one of the timers I have constructed used different component values! Just make sure Q1 will saturate and that the potential on pin 2 of the 555 will rise above 5 volts after C3 charges.

Installation

Finding a convenient location for the timer may be the most difficult part of the project, especially if a factory-installed defroster and switch are to be modified. There is usually very little extra space behind the dashboard, and Murphy's Law says that if there is extra space it will be located so as to be least useful.

If a relay is not used, an acceptable solution might be to mount the timer right at the defroster grid's terminals or just on the other side of whatever hole the wires go through. Since the circuit can be made reasonably small, it might not be objectionable if left in the open.

After-market add-on defrosters should make for an easier job. There is probably enough room near the switch to install the circuit.

Many defroster switches have an indicator light incorporated into the same package. A suggested method for using this type of switch/light combination is shown in Fig. 5.

As with any electronics, care should be taken to install the circuit so that it will not accidentally contact metal and short out. I chose to let the circuit be supported by its connecting wires and insulated it by wrapping it in several layers of electrical tape.

Final Comments

All three timer circuits have been tested in my cars. Although the timer chip I used (an NE555) is rated for the "commercial" temperature range—zero to 70 degrees centigrade—the circuit still worked well when temperatures dropped to about minus 15° C. A military temperature range (−55° to +125° C) version, an SE555 for example, would increase low-temperature reliability, but I have not been able to locate a source for this version. ■

BARTER 'N' BUY

73 CLASSIFIED ADVERTISING

RATES

Individual (non-commercial) .... 15¢ per word
Commercial .... 50¢ per word

Prepayment by check or money order is required with your ad. No discounts or commissions are available. Please make your payment to *73*. Rates for multiple insertions are available on request.

ADVERTISING COPY

Advertising must pertain to amateur radio products or services. No special layouts or positions are possible. All advertising copy must be submitted typewritten (double-spaced) and must include full name and address. Copy limited to 100 words, maximum. Count only words in text. Address, free.

73 cannot verify advertising claims and cannot be held responsible for claims made by the advertiser. Liability will be limited to making any necessary correction in the next available issue. *73* reserves the right to reject any copy deemed unsuitable.

DEADLINES

Copy must be received in Peterborough by the 5th of the second month preceding the cover date. If copy is received after the deadline, it will be scheduled to run the following month, unless specifically prohibited by the advertiser.

MATERIALS

Send to Advertising Department, *73*, Elm Street, Peterborough NH 03458.

MOBILE IGNITION SHIELDING. Free literature. Estes Engineering, 930 Marine Drive, Port Angeles WA 98362. BNB006

WANTED: Cash paid for used SPEED RADAR EQUIPMENT. Write or call: Brian R. Esterman, PO Box 8141, Northfield IL 60093; (312)-251-8901. BNB030

MILITARY TECHNICAL MANUALS for old and obsolete equipment. 60-page catalog, $3.00. Military Technical Manual Service, 2266 Senasac Ave., Long Beach CA 90815. BNB045

MAGICOM RF SPEECH PROCESSORS—Add 6 dB of average output with genuine rf clipping in your transmitter's i-f stage. Custom engineered for Kenwood TS-120, TS-130, TS-430, TS-520, TS-530, TS-820; Drake T-4X, TR-7; Yaesu FT-102. Excellent speech quality, simple installation, affordable prices! SASE for data and cost. Magicom, PO Box 6552A, Bellevue WA 98007. BNB101

REPAIR, alignment, calibration. Collins written estimates, $25; non-Collins, $50. K1MAN, (207)-495-2215. BNB117

IMRA—International Mission Radio Association helps missionaries by supplying equipment and running a net for them daily except Sunday, 14.280 MHz, 1900–2000 GMT. Br. Bernard Frey, 1 Pryer Manor Rd., Larchmont NY 10538. BNB123

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Pikesville MD 21208

Chalk up another victory for the pirates. Calm down Pittsburgh, not the ones that played our Orioles a few years back, I am talking about the software variety.

I have been gently nudging my acquaintance out west, Clay Abrams, to try to adapt some of his CoCo® RTTY software to the newer versions of the TRS-80C Color Computer® and to add disk capabilities. Well, Clay has written me that, for a variety of reasons, such a version will not be forthcoming. One of the major reasons that Clay has come to this decision is that there appears to be a huge number of bootlegged copies of his tape-based programs in circulation. Huge, that is, when compared to the number he has sold. So Clay has come to the conclusion that it is not worth investing large amounts of time and sweat into a program only to have it circulated "freebie-style" between buddies. Flattery is nice, but it don't pay the bills.

So look for more of Clay's work not in a catalog, but in the pages of this and other magazines. By publishing what he writes, he can realize a return on his effort and make the information available to interested individuals.

As for my efforts along the same lines, I am continuing to dabble and will either publish a set of routines here (in serial fashion) or try to organize them into an article for independent publication. Stay tuned.

Along these lines, regards to Frank Fields KB0QJ who is using a CoCo under Clay's original program. Keep up the spirits, Frank. With the capabilities inherent in the CoCo, I am sure that a program will appear on the scene which will run rings around those available for other small computers.

Along the line of useful tidbits comes a letter from Ocean City, Maryland. In this vacation haven of Maryland lives Jim Conner W3HCE, an old-time RTTY buff from the "old school," as he puts it. Jim is an active amateur on the Maryland eastern shore, using a local two-meter repeater for VHF RTTY operation. He picked up the new Heathkit HD-3030 RTTY terminal interface. This $250 box is a combined terminal unit and AFSK generator, sort of a RTTY modem, which appears to have great capabilities (according to the catalog blurb). Maybe I can convince Benton Harbor to spring for some more information on it in the future.

Anyway, Jim thought that the utility of the HD-3030 would be enhanced if an interface between it and his piles of ham gear could be designed. His intent was to be able to operate either on Morse or RTTY on both the HF and VHF bands, allowing for monitoring of the signals and control of the transmitter push-to-talk (PTT) line; features which the HD-3030 lacks.

Attacking the PTT problem head on, Jim found that while the voice-operated transmit switch (VOX) on most HF transmitters allowed operation unmodified with that mode, there was no convenient way to key the PTT line on the VHF transmitter. Digging into the HD-3030 revealed that the send-receive push-button is a double-pole switch, with only one pole being used. Running a wire from the unused side of the switch to pin 23 on the DB-25 connector, an unused pin, and to ground on the other side of the switch provided a convenient added PTT switch, appropriately labeled, with minimal modification to the HD-3030 itself.

He then used a four-position, seven-pole rotary switch to select which of four modes—VHF MCW, VHF RTTY, HF CW, or HF RTTY—is to be operated. The switch used is a Centralab PA-1027, an eight-pole, five-position switch which is only partially used. You may have to try some of the larger parts jobbers in your area to find this switch. To help shield the

PARTS LIST

Cabinet		
1	Switch, rotary, Centralab PA-1027 (8 Pole, 5 Position)	
1	Cabinet	270-269
2	4-pin mike sockets	274-002

1	3.3k-Ohm, 1/4-Watt resistor	271-1328
1	1k-Ohm, 1/4-Watt resistor	271-1321
1	10k-Ohm, 1/4-Watt resistor	271-1335
1	5k-Ohm, PC-type potentiometer	271-217
1	10k-Ohm, PC-type potentiometer	271-218
2	0.0047-μF mylar™ capacitors	Jameco MY.0047/100

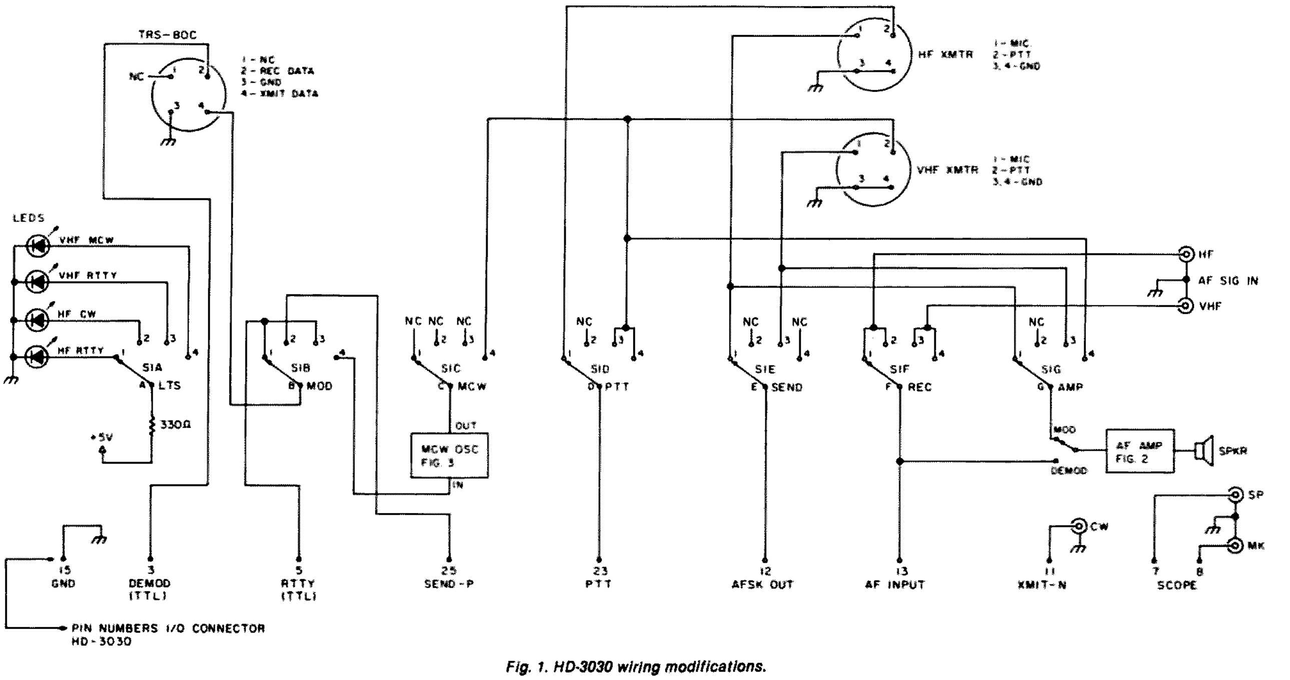

Fig. 1. HD-3030 wiring modifications.

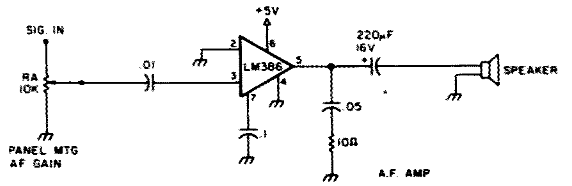

Fig. 2. This circuit adds an audio output to the HD-3030.

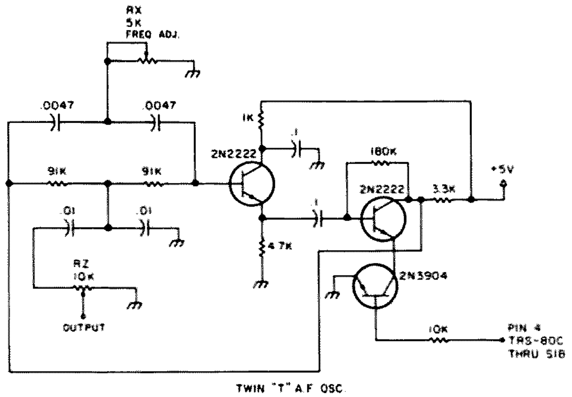

Fig. 3. A twin-T audio oscillator used to generate MCW.

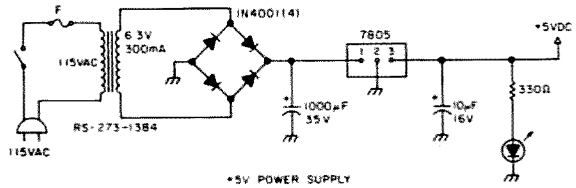

Fig. 4. An easily constructed 5-volt power supply.

cabling from floating rf, the wires between the HD-3030 and the interface box were all enclosed in a braided shield removed from an old coaxial cable. Fig. 1 shows the wiring of the main interface unit.

Several auxiliary boards were also constructed to add a few features here and there. Fig. 2 shows a small audio amplifier, based on the LM386 op amp, which is used to drive a small speaker with either the transmit or receive audio. Although the HD-3030 is able to receive modulated CW (MCW), it cannot generate this type of signal. Therefore, Jim used a classic circuit, the twin-T audio oscillator, to generate the audio waveform which the computer can turn on and off in order to transmit MCW. This circuit is shown in Fig. 3.

A rather conventional five-volt power supply runs the whole thing, and Jim's version is shown in Fig. 4. Except for the Centralab switch, all of the parts used in the interface are available from a variety of sources. The parts list gives a Radio Shack part number for all parts available there. Those few that are not carried at the Shack can be found in the Jameco catalog or on the wall of an independent electronics store. It would appear that even if you live in the middle of nowhere, you should be able to obtain the parts by mail order.

Jim drives the HD-3030 and his RTTY station with a program running on a TRS-80C. He did not specify which program he uses, but I would not doubt if it is Clay Abrams' NEWRTTY that we talked about earlier. Well, Jim, this looks like a very fine piece of work, and I am sure that the crowd appreciates your sharing it with us.

For those of you who have been looking for RTTY mailboxes, the coming months' "RTTY Loops" will be just the ticket. I have received quite a few listings and will put them all together for your enjoyment. I will also have the usual December shopping spree, a feature I know you enjoy by your comments. Also, the first four issues of "RTTY Loop" extracts remain available. Send $2.00 for each issue desired with a self-addressed, stamped envelope for each issue to the above address. If you would like a listing of what's available, just send the SASE. I especially appreciate all the nice comments I have been receiving lately, particularly those which say that when the new *73* arrives, the first place you turn is back here, to "RTTY Loop!"

SATELLITES

USING THE AO-10 APOGEE PREDICTIONS

Apogee predictions for the month of November are provided for three sections of the United States: Washington DC at 39N 77W, Kansas at 39N 95W, and California at 38N 122W. Times are in UTC and apogee in this case is mean anomaly 128 rounded to the nearest whole hour. Use the chart as a guide in aiming your antenna, then fine-tune the azimuth and elevation values to peak the satellite's beacon signal. If you require more accurate orbital predictions, contact AMSAT at PO Box 27, Washington DC 20044.

SPECIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

ALBUQUERQUE NM
NOV 3

The UNM ARC and the Westside ARC will jointly sponsor a tailgate swapfest on November 3, 1984, from 10:00 am to 2:00 pm MST, on the UNM North Campus parking lot, corner of University Boulevard and Tucker Avenue, Albuquerque NM. Admission is free; bring your own tables as none will be furnished. Talk-in on 147.75/147.15 MHz and 449.3/444.3 repeaters. For further information, send an SASE to Gary Bonebrake K8BI, 974 Arkansas SE, Rio Rancho NM 87124, Robert Scupp WB5YYX, 648 Marquis Drive NE, Albuquerque NM 87123, or Jay Miller WA5WHN, 4613 Jupiter NW, Albuquerque NM 87107, or via 3.939 MHz, 0100 UTC daily.

SOUTH GREENSBURG PA
NOV 3

The Foothills ARC will hold its sixteenth annual hamfest on Saturday, November 3, 1984, at St. Bruno's Church, South Greensburg PA. Tickets are $2.00 each or 3 for $5.00; indoor flea-market tables are $5.00. Refreshments and food will be available. Talk-in on 147.78/.18. For further information, advance tickets, or tables, contact Ronald Naviglia WA3HOL, or write FARC, PO Box 236, Greensburg PA 15601.

SELLERSVILLE PA
NOV 4

The R. F. Hill Amateur Radio Club will hold its annual indoor Winterfest on Sunday, November 4, 1984, beginning at 8:00 am, at the Sellersville National Guard Armory (located approximately 5 miles from the Pennridge Airport, halfway between Philadelphia and Allentown, near the junction of PA Routes 309 and 563), Sellersville PA. Entry is $2.00 and non-ham spouse and children are admitted free when accompanied by a paying ham. Indoor spaces (6' × 6') are $6.00 each and outdoor spaces (1 parking-space-width frontage) are $4.00 each. The purchaser of vendor space will receive a single admission and must supply his own table. Food will be available on the premises and restaurants are nearby. Talk-in on 145.19(R), 148.88(R), and 146.52 (simplex). For vendor-space reservations, write PO Box 29, Colmar PA 18915, or phone (215)-721-0278 (call will be returned collect during the evening). Because there is no discount for advance purchase of entry, buyers are encouraged to purchase admission at the gate.

GRAYSLAKE IL
NOV 4

The Waukegan Civil Air Patrol will hold its 4th annual hamfest on Sunday, November 4, 1984, from 0700 to 1700, at Lake County Fairgrounds, Rtes. 45 and 120, Grayslake IL. Admission is $3.00 and tables are $5.00. For further information and reservations, send an SASE to CAP, 637 Emerald, Mundelein IL 60060.

TAYLOR MI
NOV 4

The RADAR eighth annual Swap and Shop will be held on November 4, 1984, from 8:00 am to 3:00 pm, at Kennedy High School in Taylor MI. Activities and forums are scheduled and free parking will be available. For more information, send an SASE to RADAR, Inc., PO Box 386, Taylor MI 48180, or call (313)-291-2298.

MONTVALE NJ
NOV 10

The Stateline Radio Club of New York and New Jersey will hold RadioExpo '84 on Saturday, November 10, 1984, beginning at 8:00 am, rain or shine, at Pascack Hills High School, Grand Avenue and Spring Valley Road, Montvale NJ. Take New York State Thruway south to the Schoolhouse Road exit, then south on Schoolhouse/Spring Valley Road; or take Garden State Parkway north to Exit 172, then east on Grand Avenue. Donations are $3.00 each (available only at gate). Tables are $10.00 by mail prior to October 31st and $13.00 at the gate; tailgaters' fees are $5.00 by mail prior to October 31st and $7.00 at the gate. Doors open for vendor setups at 6:00 am. Features will include FCC license exams through Extra class, DX films and forums, multimedia programs, a transceiver clinic (HTs checked free of charge), a food concession, and ample parking. Talk-in on 146.835 repeater and 146.565 simplex. For further information, contact Robert Greenquist, PO Box 325, Montvale NJ, or phone (201)-666-3902, day or evening.

WEST CONCORD MA
NOV 10

The 35th annual New England DXCC Dinner will be held on November 10, 1984, at the Concord Lodge of Elks, Baker Avenue, West Concord MA (near Routes 2 and 62). Activities will begin at 2:00 pm with a variety of DX talks and slide programs including video tapes of VU7WCY and XU1SS. The charge for the afternoon session is $2.00. The cocktail hour will be at 6:00 pm and at 7:30 pm, a seven-course, family-style roast beef dinner will be served. The banquet speaker will be Fred Laun K3ZO (ex-HS1ABD). The charge for the evening is $14.95. For more information, contact Steve Tolf K1ST, 12 Phylmor Drive, Westboro MA 01581.

WEST MONROE LA
NOV 10

The Twin City Hams will sponsor an all-indoor hamfest on Saturday, November 10, 1984, from 9:00 am to 3:00 pm, at the Convention Center, N. 7th Street, West Monroe LA. Features will include exams, swap tables, new-equipment dealers, and a ladies' program. Talk-in on 146.25/.85. For

✓ See List of Advertisers on page 88

more information, contact Benson Scott AE5V, 107 Contempo, West Monroe LA 71291.

NEWMARKET ONT CAN
NOV 10

The York Region ARC will present the 8th annual Newmarket Flea Market on Saturday, November 10, 1984, beginning at 0800, at the Newmarket Community Center, Civic Drive, Newmarket (just north of Toronto). Admission is $2.00 per person and children under 12 will be admitted free. Table rentals are $3.00 each plus general admission and will be held only until 0800 unless payment is made in advance (setup is at 0630). Refreshments will be available. For table reservations (include a check or money order made out to the York Region ARC) or more information, contact Geoffrey Smith VE3KCE, 7 Johnson Road, Aurora, Ont., Canada L4G 2A3, or phone (416)-727-6672 (evenings).

STONE MOUNTAIN GA
NOV 10-11

The Alford Memorial Radio Club will host the 12th annual Stone Mountain Famvention on November 10-11, 1984, at Stone Mountain Park, Stone Mountain GA. Hours on Saturday are 9:00 am to 5:00 pm and on Sunday, 9:00 am to 3:00 pm. Admission is $4.00, which includes admission for both days, parking at the hamfest site, and the Saturday-night cookout. Activities will take place at Lakeside Center, with inside dealer displays and light refreshments in the Hospitality Room. The Boneyard Mile will be just outside and a full-hookup campground is adjacent. Plans are at this time to give exams, Novice through Extra class, at the Stone Mountain Inn on Saturday and Sunday beginning at 8:30 am. Talk-in on 146.16/.76. For more information, write Jim Garner KE4BI, 490 Village Green Court, Lilburn GA 30247, or phone (404)-921-7588.

VETERANS DAY SPECIAL EVENT
NOV 10-11

The Armored Force Amateur Radio Nationwide Emergency Team (A FAR NET) will sponsor a Veterans Day activity for the amateur community on the weekend of November 10 and 11, 1984. Member stations will participate as special-event stations for the net. A special commemorative certificate will be available to all amateur stations that make contact with one member station. Net stations will operate on the Veterans Day weekend from 1200 GMT on Saturday, November 10, 1984, through 2400 GMT on Sunday, November 11, 1984. Primary frequencies will be as follows: 7285 kHz, 14,325 kHz, 21,375 kHz, and 28,640 kHz (plus or minus QRM). To obtain the certificate, send a QSL and a large SASE to the net's manager, Alfred G. Beutler, 36 Manchester Rd., East Aurora NY 14052.

NORTH HAVEN CT
NOV 11

The Southcentral Connecticut Amateur Radio Association (SCARA) will hold its 5th annual Electronics Show and Flea Market on Sunday, November 11, 1984, from 9:00 am to 3:00 pm, at the North Haven Recreation Center, Linsley Street, North Haven CT. Admission is $1.50 and children under 12 accompanied by an adult will be admitted free. Tables are $10.00 in advance for the main hall and $12.00 at the door. (Reservations are strongly advised.) Setup will be at 8:00 am, and for new-equipment vendors, a special exhibit area with setup security arrangements will be made available. There will be food both at the food booth and from a mobile cart. Features will include the latest in ham radio, computers, and electronics. Talk-in on 146.01/146.61 (W1GB). For more information, directions, and reservations (make checks payable to SCARA), send an SASE to Tony Vanacore AK1O, PO Box 81, North Haven CT 06473, or phone (203)-484-4175 (home) or (203)-239-5321, extension 311 (days).

FORT WAYNE IN
NOV 11

The Allen County Amateur Radio Society, Inc., will sponsor the 12th Fort Wayne Hamfest on Sunday, November 11, 1984, from 8:00 am to 4:00 pm, at the Allen County memorial Coliseum, Coliseum Boulevard (US 30) at Parnell Avenue. Tickets are $3.00 in advance and $3.50 at the door. Tables are $8.00 and premium tables are $20.00. Vendor setup is from 5:00 am to 7:00 am. No tables will be sold at the door, and the ticket- and table-reservation deadline is October 20th. Activities will include a large indoor flea market, commercial vendors, the Ham Band under the direction of Luke Matthew WB9EWJ, and all classes of radio exams (send Form 610 and an SASE to VE Coordinator, FWRC, PO Box 15127, Fort Wayne IN 46885, by October 26th). Talk-in on .88. For tickets, tables, or more information, contact Hamfest Chairman AC-ARTS, PO Box 10342, Fort Wayne IN 46851, or call Dave Smith KA9FFT at (219)-493-2439.

MASSILLON OH
NOV 11

The Massillon ARC will sponsor Auctionfest 84 on November 11, 1984, at the Massillon K of C Hall, off Route 21, Massillon Ohio, from 8:00 am to 5:00 pm. Sellers' setup is at 7:00 am. Admission is $2.50 in advance and $3.50 at the door. Tables are available at $7.00 per 8-foot space. Refreshments are available and there will be a sit-down dinner. There will be plenty of free parking. The auction starts at 11:00 am. Talk-in on W8NP, 147.78/.18. For advance registration or information, send an SASE to MARC, 920 Tremont Avenue SW, Massillon OH 44646.

PENANG, MALAYSIA
NOV 16-18

The Malaysian Amateur Radio Transmitters Society (MARTS) will host the 14th SEANET Convention on Friday, Saturday, and Sunday, November 16-18, 1984, at the Eastern and Oriental Hotel, Penang, Malaysia. Features will include symposiums, luncheons, tours, and rag-chewing. For more details, contact Malcolm Westwood, Organizing Secretary, SEANET, PO Box 13, Penang, West Malaysia.

BILLERICA MA
NOV 17

The Honeywell 1200 Radio Club and the Waltham Amateur Radio Association will hold their annual amateur-radio and electronics auction on Saturday, November 17, 1984, beginning at 10:00 am, at the Honeywell Plant, 300 Concord Road, Billerica MA (Exit 27 off Route 3). There will be a snack bar, a bargain parts store, and free admission and parking. Talk-in on 147.72/.12 and 146.04/.64 (club-sponsored repeaters). For more information, contact Doug Purdy N1BUB, 3 Visco Road, Burlington MA 01803.

PLYMOUTH MA
NOV 22

A special-event station (WA1NPO) from Plymouth, Massachusetts (America's Hometown) will be sponsored by the Whitman Amateur Radio Club and Plimoth Plantation on Thanksgiving Day, November 22, 1984. An attractive certificate suitable for framing will be issued to any foreign or domestic amateur who makes contact with this station, which will operate from 9:00 am until 3:00 pm. The station will be in operation at the Plimoth Plantation from an indoor site in the museum's 1627 Pilgrim Village.

Frequencies are as follows: 1300 to 1430 GMT—21.260 MHz; 1430 to 1730 GMT—7.280 MHz ± QRN and/or 7.050 MHz (CW); 1730 to 2000 GMT—21.385 MHz; 1300 to 1600 GMT—14.255 MHz or 14.180 MHz; 1400 to 1500 GMT—14.025 ± QRM; 1600 to 2000 GMT—14.345 MHz. There will be limited 2-meter operation on the local club repeater (tentative): 147.225/.835 and 146.52 simplex.

A UK club station is planning to participate: GB2UST (United States Thanksgiving) on 20m and 15m and GB4UST on 80m and 40m; they have some forty acres in which to erect antennas.

To receive a certificate, send proof of contact and $1.00 or four IRCs to the Whitman ARC, PO Box 48, Whitman MA 02382.

GREENSBORO NC
NOV 24-25

The 4th annual Greater Greensboro Hamfest will be held on November 24-25, 1984, from 9:00 am to 5:00 pm, at the National Guard Armory, 1100 Franklin Boulevard, Greensboro NC. For advance tickets, send an SASE to Fred Redmon N4GGD, 2305 Sherwood Street, Greensboro NC 27403. For dealers' space, tables, and flea-market information, contact Coy Hennis WD4NHL at (919)-294-2841.

OAK PARK MI
NOV 25

The Oak Park High School Electronics Club will hold its 15th annual Swap 'N' Shop on Thanksgiving Sunday, November 25, 1984, from 8:00 am to 4:00 pm, at the Oak Park High School, Oak Park MI. The doors will open at 6:00 am. Admission is $2.00 and 8-foot tables are $6.00. Refreshments will be available. For more information, send an SASE to Herman Gardner, Oak Park High School, 13701 Oak Park Boulevard, Oak Park MI 48237, or phone (313)-968-2675.

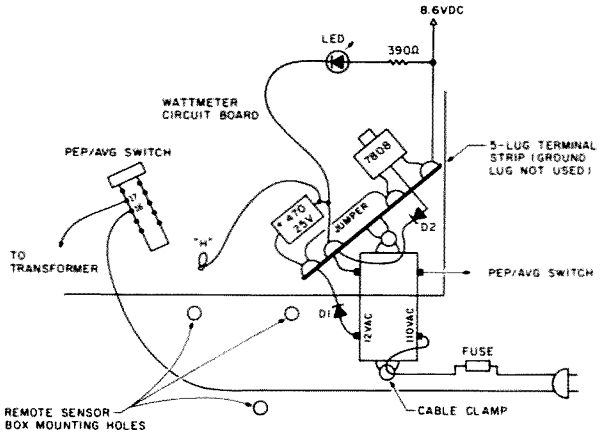
STONY BROOK NY
NOV 25

The Radio Central ARC will present the 6th annual ARRL Ham-Central on Sunday, November 25, 1984, from 9:00 am to 3:00 pm, in the social hall of Temple Isaiah, 1404 Stony Brook Road, Stony Brook, Long Island NY. General admission is $3.00 and children under 12 and XYLs will be admitted free. An 8-foot table space is $7.00 and includes one free admission. Doors will open at 7:30 am for dealers and sellers (ham-related items only). There will be food, drinks, and free parking available. Seminars will feature speakers Gerry Hull VE1RM/W1 on the St. Paul Island DXpedition of 1983, Paul Beeman KA2MUM with an OSCAR lecture and slide show, and Art Greenberg W2LH and Madeline Greenberg W2EEO with an antenna lecture. Talk-in on 144.550/145.150 and 146.52. For reservations and more information, contact Bob Yarmus K2RGZ, 3 Haven Court, Lake Grove NY 11755, or phone (516)-981-2709 Monday through Friday after 6:00 pm.

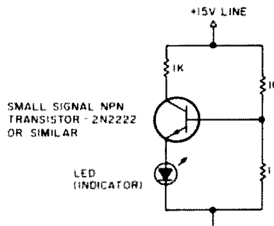
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you a one-year subscription (or extension), to be sent upon publication. Submit your idea to: Circuits, Editorial Offices, 73 Magazine, Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.

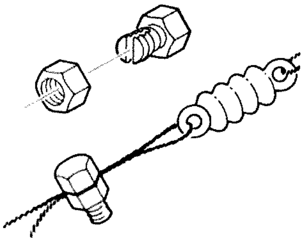


SELF-CONTAINED BATTERY ELIMINATOR FOR THE HEATH HM-2140: This simple circuit is built into the wattmeter cabinet and doesn't interfere with the internal mounting of the remote sensor box. The PEP/AVG push-button switch has an extra set of contacts which can be used to switch the power supply on when PEP readings are desired. The LED is centered between the meters on the front panel. The fuse holder can be an inline type or be mounted on the circuit board behind the battery clip. Note that the negative side of the power supply does not go to ground. If you don't plan portable battery operation in the future, the 8.6-V output can be permanently wired to lug 2 of the PEP/AVG switch. The transformer is mounted between the existing screw near the battery clip and a spacer installed on the bottom cabinet. A five-lug terminal strip mounted with the transformer at the corner of the circuit board will hold the other components, and a cable clamp on the other side of the transformer secures the line cord. If a type 7808 three-terminal regulator is not readily available, an LM317T adjustable regulator (Radio Shack #276-1778) can be substituted.—Wayne Arnett AI7C, Chandler AZ.

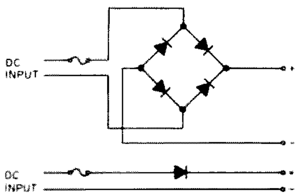


CIRCUIT FOR "SMART PANEL LAMP" AS DESIGNED FOR REGULATED 15V LINE

SMART PANEL LAMP: This power-on indicator for your regulated 15-V supply also indicates overload conditions (current-induced voltage drop) and can be easily modified for other voltage levels. Two resistors sample the output voltage and compare it with the 2.2-V reference defined by the LED and transistor emitter-base-junction voltage drop. If the regulated 15-V line drops by about a volt, the indicator LED goes out. The 1k resistor in the collector circuit limits the current draw to 15 mA so the indicator won't burden the supply.—Penn Clower W1BG, Andover MA.



INVERTED-V TUNING TRICK: Tuning the inverted-V antenna requires adjustment of both the enclosed angle and the length of each side of the dipole. You can take the pain out of length adjustments by fastening the ends to the insulators with split bolts. These come in various sizes, and I recommend using the kind made from bronze.—Wm. Bruce Cameron WA4UZM, Temple Terrace FL.



POLARITY PROTECTION FOR PLUG-IN RADIOS OR OTHER SOLID-STATE DEVICES: By adding a diode or a diode bridge in the dc power-input circuit, you can have complete protection against ever connecting the unit backwards. With the bridge circuit, it makes no difference which way the connection is made. However, if the diode is connected in reverse, there will be no current to the unit due to blocking action of the diode. When connected correctly, diode will conduct and the unit will work. Using this with plug-in radios, mount the bridge or diode inside the chassis. Be sure the bridge or diode will handle the maximum current requirement.—E. A. Rowe W7PWQ, Chelan WA.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

About three years ago I built a CMOS digital thermometer out of *Popular Science* magazine. The probe uses a Texas Instruments 6.8k Tm-1/4 sensistor with a positive temperature coefficient. I haven't been able to find this part—can anyone help?

David Shoal WD4CZW
Rt. 5 Box 375
Mocksville NC 27028

Just a note to some of the readers concerning "Ham Help." If someone sends you the information you need, please send an acknowledgement back to that person, perhaps including the postage. After all, he or she went out of the way to find and copy the material for you.

I don't know how many people respond to these requests for help, but in April I mailed 78 pages of information to 7 different hams. Only one person, a teacher, returned a note of thanks. In January it was 5 sets of information—with no replies.

I'll still send the stuff out, but I wonder what happened to the spirit of amateur radio?

J.Y. Lem KB6BO
5222 Coringa Drive
Los Angeles CA 90042

Has anyone been successful in converting a Swan 500C to a 500CX? I also would like to increase the stability of the 500C, and to overcome its transmit-to-receive problem.

John Matthews K6VS
12206 Huston Street
North Hollywood CA 91607

I will pay for any data concerning the Nems Clarke UHF receiver model 2801A.

John Elmquist
3308 Bahama N.E.
Albuquerque NM 87111

I am interested in obtaining a National NCX-1000 or NCX-2000, used or reconditioned. Write with price and condition via airmail to:

Fermin Anzalaz LU1SH
PO Box 155
5300 La Rioja
Argentina, South America

I need manuals for a Lavoi spectrum analyzer LA-17 and a DEI telemetry-receiver tuning unit T-102-A (216-260 MHz). Will pay reasonable costs incurred.

Paul Veltman WA6QKQ
5333 York Drive
Fremont CA 94536

Would someone please help me find a schematic or manual for a Communications Power, Inc., model WM-1000 wattmeter? I will gladly pay for any costs incurred.

Richard Whipkey AD6X
888 Yolo Way
Livermore CA 94550

NEW PRODUCTS

JENSEN OFFERS FREE CATALOG

A new catalog of precision tools is offered free by Jensen Tools, Inc. Illustrated in full color, the 160-page catalog contains more than 3,000 tools of interest to field engineers, technicians, computer- and telecommunication-service persons, and electronic hobbyists.

Major categories covered are test equipment, soldering equipment, tweezers, screwdrivers, cutters, drafting supplies, power tools, computer accessories, circuit-board equipment, and miscellany. Also included are many new products from Jensen and over 40 pages of service kits and tool cases for electronic specialists and technicians.

To obtain a free copy, write *Jensen Tools, Inc., 7815 S. 46th Street, Phoenix AZ 85040; (602)-968-6231.* Reader Service number 482.

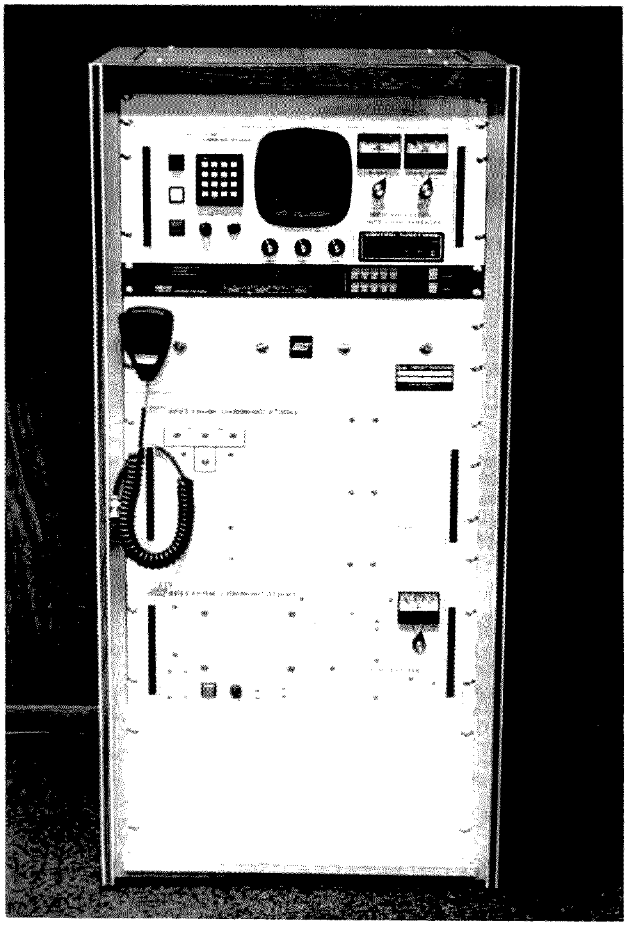
SPECTRUM COMMUNICATIONS' SCR2000X REPEATER

Spectrum Communications' SCR2000X microprocessor-controlled repeater combines the latest digital techniques with Spectrum's highly-refined rf technology to yield an advanced, high-performance repeater system.

Standard features include: full autopatch and touchtone™ remote-control capability, phone-line and over-the-air command modes, up to 13 auto-dial telephone numbers, a touchtone-to-pulse converter, full 16-digit decoding, up to 6 auxiliary functions, automatic CW identification, and built-in battery backup for the microprocessor's memory in case of a power failure.

Several power levels are available from 30 to 75 Watts on 144, 220, and 440 MHz. High-power rack-mount repeater power amps and power supplies are available up to 150 Watts.

For more details, contact *Spectrum Communications Corp., 1055 W. Germantown Pk., Norristown PA 19401-9616; (215)-631-1710.* Reader Service number 478.



Spectrum Communications' SCR2000X repeater.

DOCTOR DX BY AEA

Doctor DX by AEA is a complete CW contest simulator packaged in a plug-in cartridge for the Commodore 64. It is a computer simulation of the *CQWW DX* Contest, allowing you to work the HF bands using a computer-generated modern-style transceiver and omnidirectional antenna.

All of the stations you will work using Doctor DX are generated by the computer. As you tune up and down a particular band, you will hear stations contacting other stations, plus QRM and QRN, similar to on-the-air conditions. Station prefixes are generated according to international callsign-allocation conventions, and are weighted according to amateur-operator density. The speed of the stations at the lower end of the bands is much faster than that of stations higher up, and the low-end operators have greater "savvy."

AEA's Doctor DX contest simulator.

The propagation programmed for each band is driven by a real-time clock, with conditions varying by the time of day and band selected. Band conditions are simulated for a sunspot-cycle peak for a station using an omnidirectional antenna.

A typical two-way contact involves exchanging callsigns, signal reports, and CQWW zones. If you miss part of a report, you may ask for and receive a repeat. If you make an error, the simulated station will request a repeat. You may also request the other station to QRS or QRO.

Doctor DX approaches reality in its operation. AEA even offers award certificates to operators who work all zones, DXCC, 5-band DXCC, or qualify for the Doctor DX Honor Roll.

For detailed information on Doctor DX, contact *Advanced Electronic Applications, Inc., PO Box C-2160, Lynnwood WA 98036; (206)-775-7373.*

OMNITRONIX RS-232 INTERFACE

Omnitronix has announced the release of their Deluxe RS-232 Interface for the VIC-20, C64, and SX64. The RS-232 interface has been designed to allow easy use of any type of RS-232 equipment, including serial printers and modems. The interface plugs into the user I/O port of the computer.

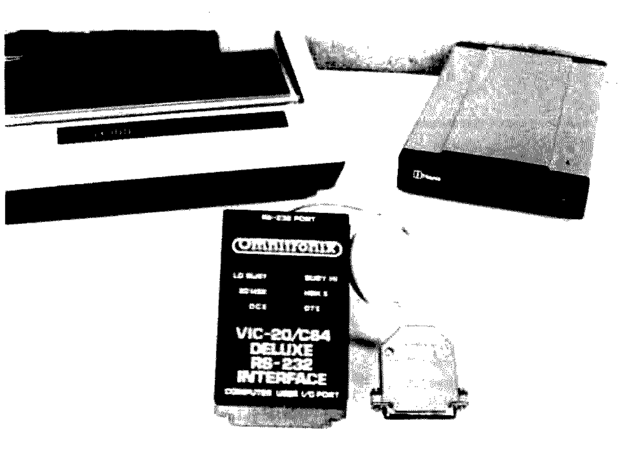
Included as part of the unit is a three-foot cable terminating in a male or female DB-25 connector. The Deluxe RS-232 Interface can also be supplied with a PC-board-mounting female DB-25, allowing it to replace the 1011A. Three switches in the case cover allow you to set the unit for DTE/DCE, invert pins 20 and 5, and select the Busy line polarity. The RS-232 interface supports virtually all RS-232 signals including Ring Detect and can operate at up to 2400 baud. The manual includes a type-in Basic terminal program and a tutorial on using the RS-232 port.

For additional information, call or write *Omnitronix, PO Box 43, Mercer Island WA 98040; (206)-236-2983.* Reader Service number 480.

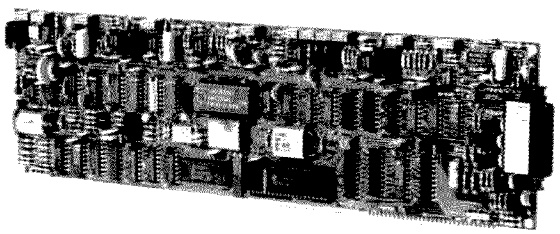
HAL'S IBM/RTTY INTERFACE

HAL Communications Corporation is offering their new PCI-2000 RTTY Interface module for the IBM-PC™. Features include full Bell 103/202 support, 170/425/850-Hz shift, direct FSK output, 45–1200-baud transmission rate, and Morse, Baudot, or ASCII codes.

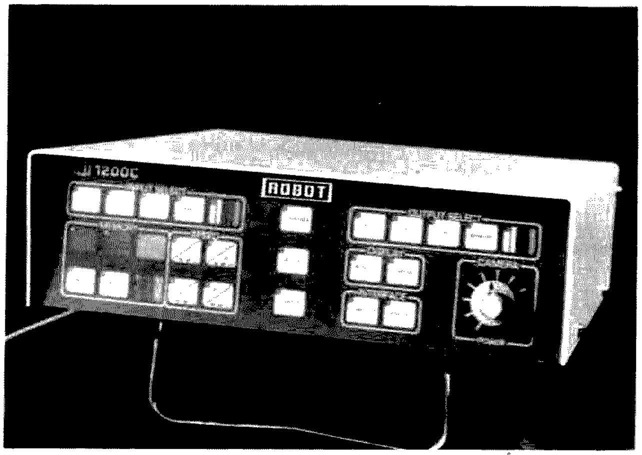
The supporting software incorporates such features as split-screen formatting, transmit and receive buffering, and disk-file storage and retrieval. All PCI-2000 parameters are set using the PC's FN keys.



Commodore RS-232 interface from Omnitronix.



HAL's IBM-PC RTTY/CW interface.



The Robot 1200C color SSTV converter.

For further information, contact *HAL Communications Corporation, PO Box 365, Urbana IL 61801; (217)-367-7373.* Reader Service number 484.

HI-RES COLOR SSTV CONVERTER FROM ROBOT

A new high-resolution color SSTV converter has been added to Robot's line of amateur-radio products. Designated the Model 1200C, it is capable of transmitting color video images that rival broadcast television in picture quality. The Model 1200C has three selectable 6-bit memory planes that combine to form 262,144 color combinations in a 256 × 240 line full-screen display.

Eight different black-and-white- and color-transmission formats are available with automatic selection on receive. Up to six separate pictures may be stored in memory. The unit accepts color or black-and-white composite video from standard TV cameras and has RGB, composite, or rf-modulated video output.

A unique feature of the Model 1200C is the 8-bit parallel I/O port for computer interfacing. This allows total access to each individual pixel by a host computer for image processing, transformation, storage and recall, and graphics. This port also allows connection to a printer for black-and-white or color hard-copy picture printing.

The Model 1200C features touch-sensitive front-panel switches for full station control and several automatic functions. Fine tuning, speed switching, and color or black-and-white detection are automatically accomplished without operator intervention.

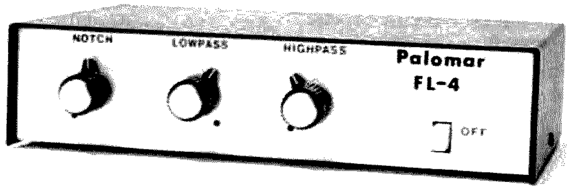
For further information, contact *Robot Research, Inc., 7591 Convoy Ct., San Diego CA 92111; (619)-279-9430.* Reader Service number 479.

UNIVERSAL AUDIO FILTER FROM PALOMAR

Palomar Engineers has announced a new universal audio filter. Model FL-4 is for SSB/CW/RTTY and features switched-capacitor filters. A 10-pole low-pass and an 8-pole high-pass can be moved anywhere in the 200-3500-Hz range to form a sharp bandpass filter at any frequency and of any bandwidth. A notch filter is also included.

The filter connects to the receiver's phone jack and provides 2 Watts of audio to drive a speaker. The on-off switch bypasses the filter when not in use. It operates from 15 V dc.

For further information, contact *Palomar Engineers, Box 455, Escondido CA 92025.*



The Palomar FL-4 Universal Audio Filter.

SIMPSON PANEL METER CATALOG

Simpson Electric Company is offering a new four-color catalog, number 5400-P. The catalog lists the entire Simpson line of over 1500 US-made analog and digital panel meters, meter relays, and controllers. Also listed are panel-mount chart recorders.

Simpson, manufacturer of the world-famous 260® VOM, is a member of the Katy Industries, Inc., Electrical Equipment and Products Group. For a free copy of Simpson Catalog 5400-P, write to *Simpson Electric Company, 853 Dundee Avenue, Elgin IL 60120-3090; (312)-697-2260.* Reader Service number 483.

ISS HALON EXTINGUISHERS

International Safety Systems, Inc., (ISS) has announced two fire-fighting products designed specifically for consumers, using Halon, a colorless, odorless, electrically nonconductive vapor.

Halon chemically interferes with the combustion process by breaking up its complex chemical reactions, while other extinguishing agents only smother the fire. It is extremely low in toxicity, does not damage property, leaves no residue, and has a twelve-year shelf life.

ISS's Halon products consist of two models; the 12-C and the 24-H, containing .75 lbs and 1.5 lbs of Halon, respectively. The smaller 12-C is ideal for placement in an auto glove compartment or in a kitchen. The 24-H is excellent for a light aircraft, camper, or workshop.

For further details, contact *ISS, 2227 Idlewood Rd., Suite 4, Tucker GA 30084.* Reader Service number 485.

REVIEW

BREAK COMMUNICATIONS SYSTEMS EQUIPMENT CONSOLE

Amateur equipment comes in all shapes, sizes, and levels of complexity. But whether you're using the latest solid-state marvel or a venerable old "boat anchor," one piece of gear is an absolute necessity: some sort of operating table or console.

After years of operating from various tables with mixed results, I recently took the plunge and acquired an equipment console from Break Communications Systems (BCS), Inc. It not only provides a convenient and rugged operating position, it's also a superb-looking piece of furniture.

Description

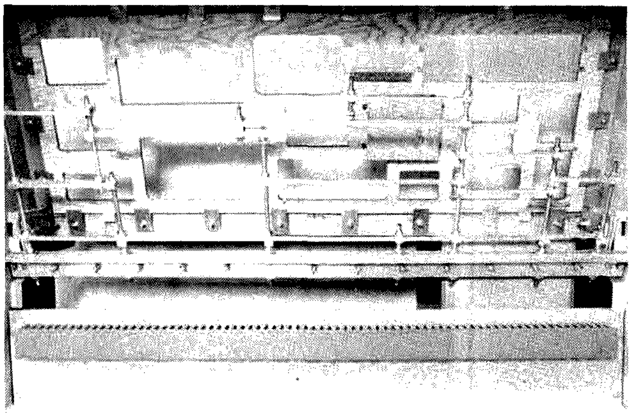
As the photos show, the BCS console consists of a desk top or writing surface and a gently sloped front panel with cutouts to allow the front of each piece of equipment to protrude through. Behind the front panel is an aluminum and steel support rigging that carries most of the weight of the gear. The holes in the front panel are cut by a computer-driven saw to fit precisely around the equipment with little or no "slop." The front panel is attached to the console with a number of heavy steel clamps, allowing replacement of the panel when new equipment is acquired.

The console is constructed of hardwood, 1/2" and 3/4" plywood, and 1/2" particle board. BCS consoles are covered in a high-pressure laminate (the generic name for materials such as Formica). Standard consoles are four, six, or eight feet wide and weigh from 150 to 350 pounds without radio gear. Many accessories and options are also available, as are L- and U-shaped consoles.

Designing The Console

No two hams have the same radio gear or operating habits. Therefore, the ideal operating console should be customized for every ham. The key to customization in the BCS design is the front panel, which is cut to accept the equipment in any arrangement desired by the customer. BCS has developed some interesting techniques that allow the creation of front panels with precisely-cut equipment holes without the need to actually lay their hands on the gear. Getting the console exactly right becomes a cooperative effort between BCS and each customer.

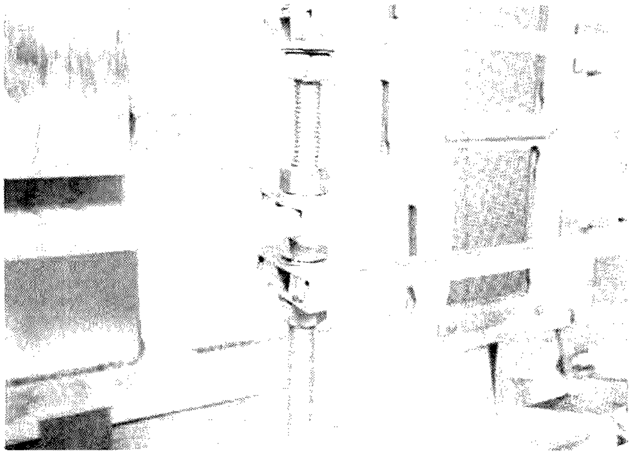
Once the basic size of the console is selected (for my equipment, a six-footer was just right), then begins the process of determining the exact size and shape of each hole BCS will cut in the front panel. It starts with BCS sending the customer a basic measuring kit and wooden templates or "test cuts" for any of the gear for which BCS has previously cut front-panel holes. The customer must carefully measure any equipment BCS has not dealt with before. Also, each template must be carefully checked to see that it fits per-



Rear view of BCS console, showing the equipment support rigging, the cutouts in the front panel for radio gear, and the steel clamps (around the perimeter) which hold the front panel in place.

fectly around the front of its respective gear. It turns out that manufacturing tolerances allow for considerable variation in the dimensions of rigs of the same model, so BCS gives customers a special form on which to indicate how each template must be modified for a perfect fit.

All measurements and template modification instructions are phoned or mailed to BCS, which then sends out a complete new set of wooden templates for any rigs that weren't perfect the first time. This sequence of template modification followed by new templates continues until the customer has a template that fits each piece of gear as precisely as possible, the goal being no more than 0.03" of slop.



Closeup of a portion of the steel and aluminum support rigging. The vertical members are 1/2-inch threaded rod.

The arrangement of the equipment on the front panel is what makes the difference between a station that is easy and efficient to operate and one that is (literally) a pain in the neck. A poorly-planned layout can have the operator forever straining to reach an often-used accessory. For its part, BCS sends each customer a one-half-scale mock-up of the front panel, along with one-half-size cardboard cutouts (called "puppets") in the proper shape of each piece of equipment. It is then up to the customer to move the puppets around the front-panel mock-up until the best layout is found.

Once the templates fit properly, the front panel is laid out, all options are specified, and the color scheme is selected (not easy—there are thousands of choices!), then the console can be prepared and shipped in about two weeks. Total elapsed time from the start of the design process is six to eight weeks. It took a bit longer in my case, but only because I didn't respond as quickly as I might have when new templates were shipped to me. Total time invested on my part was less than three hours.

Performance

The BCS console is worth waiting for. Overkill is the only word to describe the protective shipping crate in which my console arrived. I've never seen sturdier packaging. Assembly was a snap, even for one person, and can easily be accomplished in an afternoon. The only tools required are 9/16" and 3/4" open-end wrenches, although a socket wrench makes the job much easier. I encountered no problems whatever.

Mounting the equipment is equally undramatic. The rugged metal support rigging was set up at the factory for my equipment layout and worked exactly as advertised—very solid. Minor adjustments were made to square up each piece of gear with the front panel, and I found it convenient to remove the rubber feet from some pieces. The console can be rolled about easily on its heavy-duty casters and the back is open, allowing access to the rear panels of all gear. There is also plenty of room in the rear of the console for accessories such as power supplies, VHF amplifiers, and other items not requiring front-panel space. An optional drawer/bookshelf unit provides a handy place to store things like logbooks, message forms, and spare fuses.

Conclusions

There are pluses and minuses to this type of operating console. On the plus side, there is the complete absence of unsightly wires and cabling, having all equipment within easy reach (yet not piled on top of itself), the convenient access to the rigs from behind, and the knowledge that if I ever buy new equipment, I need replace only the front panel and support rigging for a relatively small fee. Equally important, perhaps, is the feeling of pride one gets in operating from such an impressive looking console. It's like having a seat at mission control.

On the other hand, a ham who replaces his gear frequently, or who likes to rearrange his operating position once a month, may find it prohibitive to replace front panels so often. For my purchasing patterns and operating style, it presents no problem, as it is usually two or three years between major changes at WB8BTH.

In summary, I couldn't be more pleased with my BCS console. The workmanship is first rate, and the console is built like a tank. Larry Kushner WA6BKC/4 and his crew have done a fine job.

Prices for BCS consoles start at $600. For more information, write *Break Communications Systems, Inc., 5817 SW 21st Street, Hollywood FL 33023.* Reader Service number 486.

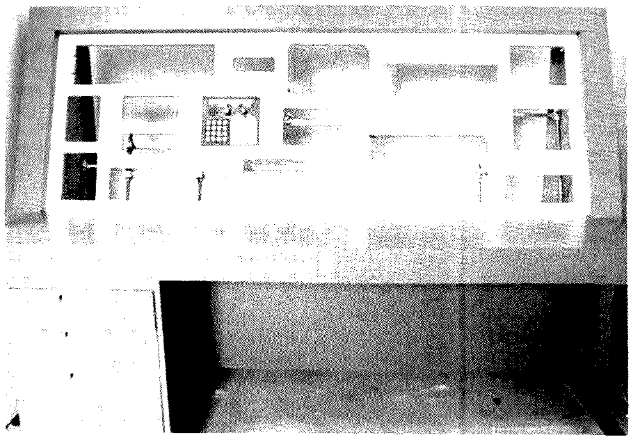
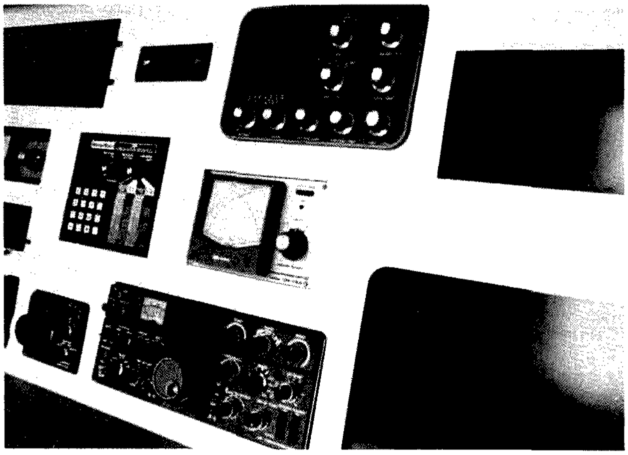
MIZUHO MINIATURE SIX-METER MULTIMODE

A couple of years ago at the Dayton Hamvention, I saw a little Japanese transceiver kit for sale. It was about the size and shape of an ICOM 2A, but it wasn't an FM rig. It was a *sideband* handie-talkie with only a quarter-Watt output; the Mizuho MX-6Z. Amusing, I thought, but not really serious. It turned up again in 1983 at Dayton and began to be advertised in the ham magazines. Three models were now available, covering 15, 6 and 2 meters, plus amplifiers for the 15- and 6-meter units and some accessories. So they *were* serious after all! Curious about what sort of rig it could be, I bought a pair of the six-meter versions. (A pair, to ensure someone to talk to. I wasn't sure what sort of 6-meter activity there was here in eastern Tennessee).

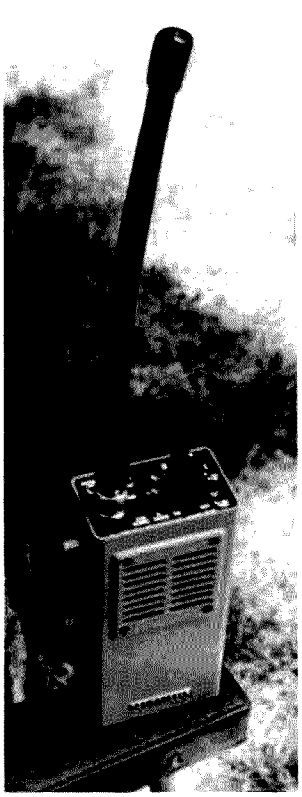
Assembling the kits turned out to be quite simple, taking only about 45 minutes each, despite some missing steps in the English-language instructions. The full Japanese instruction set was included too, with enough drawings to make up



The completed BCS console, ready to receive the station equipment. My keyer, an unusually-shaped piece of gear, is already in place, having been custom-mounted for me at the factory.



Only the faceplate of each piece of gear protrudes through the front panel, giving the console a sophisticated look.



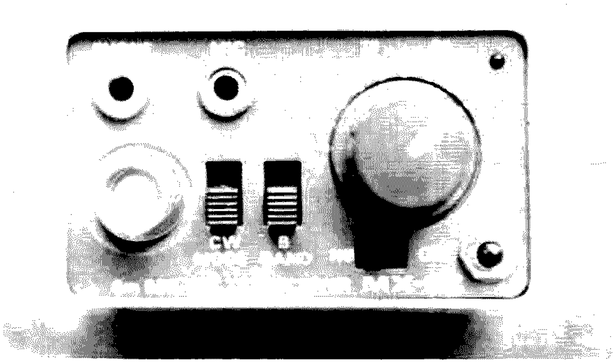
The Mizuho MX-6Z.

for the missing info. There were also some suggested modifications in the Japanese instructions, such as an S-meter (though I don't know where you'd mount it!), a transmit light, and a CW sidetone, which aren't in the English version. The two circuit boards were already assembled, tested, and mounted, leaving only a little wiring and case assembly to do. Two types of battery holder were provided; a 9-volt transistor-battery connector, and a holder for six AAA cells. I recommend the latter, since the unit draws enough current to deplete almost any 9-volt transistor battery in short order.

Both units worked as soon as power was applied, and no tune-up was necessary (no instructions were provided anyway). Initial tests with bench supplies showed a need for a little more bypassing at the external-power input jack on the bottom of the case since the supplied external-power cord was radiating more than my dummy load! A .001-uF ceramic across the dc-input terminals quieted things down. One unit put .275 Watts into the load on CW and SSB voice peaks, the other a little less. However, both drew 220 mA from the 9-V supply while doing it. Current drain on receive is about 40 mA, and 100 mA during key-up transmit. A regular carbon-zinc transistor battery went flat very quickly under the strain, so I switched to alkaline AAA cells which have held up pretty well in light usage. A separate power supply or external battery pack is really necessary for any serious long-term operating. It looks to me as if a battery pack from an ICOM 2A would fit perfectly on the bottom of the case if it could be attached securely.

Initial tests in the field (literally a field!) showed that the little units have good audio quality and frequency stability on both transmit and receive. The 11-inch "super rubber ducky" antennas supplied gave perfect copy at a range of a half mile with a hill and building in between. The tuning knob is on the top of the case and controls a variable crystal oscillator with a range of 50 kHz. A "band" switch next to it switches between either of two crystals (one is provided, for 50.2 to 50.25 MHz), giving it a total of 100 kHz of coverage. The necessity of tuning in the other station and the lack of squelch are a little strange at first when your only other hand-held experience is with 2-meter FM. Perfectly normal on HF sideband, but unexpected in a handle. The transmit button isn't a push-to-talk type. It's a latching switch—push once to transmit, again to receive. Since the MX-6Z also transmits CW (from a tiny button on the top panel or through a miniature jack on the bottom), this does make some sense. The internal microphone is an electret type, and there is an external-mike jack on top of the case next to the headphone jack. A noise-blanker switch is below the tuning knob, and the blanker does seem to work pretty well on ignition noise, an important consideration on six meters.

As you'd expect in any unit that packs this many features into so small a case, the circuitry is pretty simple. One of the two PC boards is devoted to rf, and the other to i-f, sideband generation, and audio. The receiver is a single-conversion type with a fixed-tuned dual-gate MOSFET rf-amplifier stage. I measured the sensitivity (crudely) as about 0.8 uV for 20-dB signal-to-noise; I could hear a signal at 0.1 uV. The i-f frequency is 7.8 MHz, and the tiny crystal filter seems adequate on both receive and transmit. A quick and dirty check showed a 6-dB bandwidth of about 2 kHz, from rf in to speaker out. The transmitter has three "power amplifier" stages following the transmit mixer, the first of which is a dual-gate MOSFET which is keyed for CW. All of the stages are broadly tuned and inductively coupled except the final, which is a multi-stage pi type. Transmit-receive switching is done with diodes and is accomplished with a closure to ground, so CW break-in operation might be possible with a simple modification. Audio output and quality is pretty much on a par with other handie-talkies, with an LM386 audio-amp IC driving a two-inch speaker.



Mizuho MX-6Z controls.

The best part of this little rig is that it's fun! It really works pretty well for its low power. When six is open, not much power is needed, of course, and when the band is closed, not much will help. One of the first contacts I made after building and testing my MX-6 was with a south Texas station, followed by contacts with Oklahoma and Minnesota, all between 800 and 1000 miles from my Tennessee OTH. This was done with an 80-meter dipole, since I didn't have a six-meter antenna up! A proper antenna and more power would help a lot. QRO is available in the form of a 5-Watt amplifier, the PL-6.

Ultimately, this litle rig is likely to be used for portable or mobile work such as mountaintopping. Its small tuning knob and limited tuning range, to say nothing of its low power, will not make it a favorite of hard-core six-meter operators, but it is a nice cheap way to get on six-meter sideband. I use mine mostly for local monitoring and checking for band openings, tasks for which the rubber-ducky antenna works fine. When activity occurs I can hurry to the shack and plug in the outside antenna and sharpen up my QRP operating skills. One of these days I'm going to get a portable six-meter beam and hike up into the Smokey Mountains and hope for a band opening. Then the MX-6 will really be in its element!

YAESU FT-726R

Remember the advertising bit about "Who put eight great tomatoes in that little bitty can?" I think I know who did it, and they now work for Yaesu! The features packed into Yaesu's FT-726R go beyond those of the early all-mode rigs to create a truly impressive radio. A glance at the front panel finds controls usually associated with an advanced HF rig rather than a VHF one. One's choice of options centers largely around band preferences rather than operating modes or signal processing. More about that in a moment.

The FT-726R comes with 2 meters as standard equipment, with provisions for installing two optional modules for other bands. Available modules include those for HF (15, 12, 11, or 10 meters), 6 meters, and 70 cm (430–440 MHz or 440–450 MHz), with thinly veiled rumors of forthcoming 220- and 1296-MHz modules. The optional satellite module permits full-duplex crossband operation via OSCAR or RS satellites. Operation on LSB, USB, CW, and FM is standard. No optional speech processor or noise blanker here; both are standard. As in most digitally-tuned rigs, there are two vfos plus memories, along with scanning features. A microprocessor keeps track of the mode of operation and controls the memory and scanning functions. Receiver performance is enhanced by controls for agc time constant, i-f shift, i-f width, rf gain, audio tone, and clarifier (RIT). Provision is made for installation of a CW filter.

Impressions

The review unit was equipped for the satellite enthusiast and casual operator on 2 meters and 70 cm. Modules for 2 meters, HF, and 70 cm were installed, along with the satellite unit and a 300-Hz CW filter (model YK-455.8MCN). Even after operating a variety of gear over the years, my initial reaction to the front panel was one of mild panic—how could I master all those (41!) controls? A look at the rear panel, though, found it surprisingly "clean" with jacks for key, 600-Ohm audio output, external speaker, external push-to-talk, and power. Each module has two rear-panel jacks: the separate coaxial connectors that allow bandswitching without swapping cables, and companion 3.5-mm jacks which provide ground-on-transmit to energize an external amplifier on the appropriate band. It was reassuring to find a type-N coax fitting on the 70-cm module.

It didn't take long to find room for the 726—it can replace *six* boxes in my shack! A closer look at the front panel and perusal of the operating manual showed that the controls are logically grouped, and later operating bore that out. Don't think you can make this radio do all its tricks without looking at the manual, though.

A word on the manual itself is in order here. It is definitely an *operating* manual. There is no theory of operation or detailed parts layout. Complete installation and operating instructions, schematics, and block diagrams are included, as well as procedures for installation of options. The only fault I could find with the manual turned up when I tried to operate through OSCAR 10 and the 726 seemed to get "confused." It turns out that when operating crossband full-duplex, the uplink and downlink modules must both be in CW or both be in SSB. A LSB/USB mix works; a CW/SSB combination does not. The manual isn't too clear on this.

OSCAR 10 operation was good when using a 16-element linear yagi on 435 MHz and my four-yagi EME array with tower-mounted preamp on the downlink. A later attempt on Field Day was not so successful when using the same uplink antenna and a 10-element "twist" downlink antenna with no preamp. Reasonable performance could probably be expected with circular polarization on uplink and a downlink system between the extremes tried here.

Moonbounce operation proved the worth of the i-f-shift and width controls and the 20-Hz clarifier steps in enhancing weak-signal readability. The results were so dramatic that I didn't even try the outboard audio filter I usually use. Semi-break-in CW is smooth at about 18 wpm, but the delay is too short for the slower speeds used on EME—the extent PTT could be wired with a toggle switch to get around this. Incidentally, it appears that a variable resistor (VR07 on the tx unit) controls break-in delay, but it isn't mentioned anywhere. (Nor is VR08, which controls sidetone volume. *Operating* manual, remember?).

The 726 was pressed into service on 70 cm during contest operation from a hilltop near Ithaca NY. Intermod problems from an FM station 2 miles away on the next hill disappeared when we substituted the FT-726R for our usual 432 rig. Receiver sensitivity seemed good and the transmitter drove a solid-state amplifier nicely. The other operators in our multi-op effort mastered the rig's essential controls quickly and easily.

Assorted Pluses and Minuses

The CW filter has its own front-panel

control and that's great! Hats off to the engineer who gave the filter in/out choice to the operator and made clockwise rotation of the tuning knob increase frequency. On the negative side, I found the CW sidetone clicky to the point of being slightly annoying, especially in headphones. A few spurious signals turned up in the HF region even when the antenna was replaced with a good 50-Ohm load. The spurs didn't show up on 2 meters or 70 cm. Power-line noise had to exceed S3 on the S-meter before the blanker had an effect. Suprisingly, the blanker could do nothing with ignition noise from my neighbor's lawn mower. It's obvious that noise rise time and level both determine how effective the blanker will be.

The Bottom Line

Overall, the FT-726R gets very good marks. Any faults I have noted are minor in comparison to its performance and features. It is evident that a lot of common-sense thinking went into the design of this rig. Learning to sort out all the controls was painless with the aid of the manual. The ability to hop back and forth between a 10-meter sporadic-E opening and 432-MHz activity at the flip of a switch is quite remarkable. Even while writing this, I'm letting the rig scan the various calling frequencies in hopes that one of the bands will open!

For further details, write or call *Yaesu Electronics Corporation, 6851 Walthall Way, Paramount CA 90723; (213)-633-4007*. Reader Service number 476.

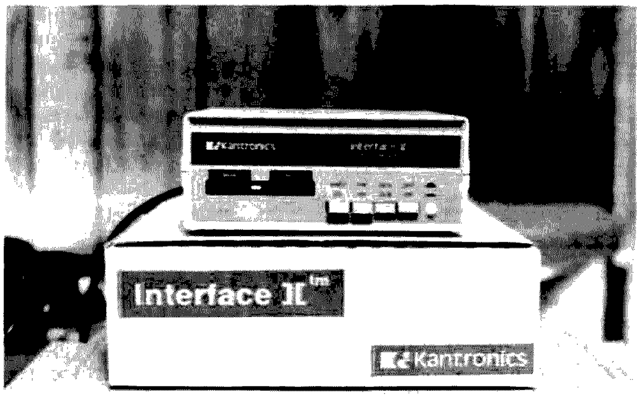
THE KANTRONICS INTERFACE II



The Kantronics Interface II

As an amateur enthusiast of some twenty-four years turned computer crazy, I am particularly interested in software and hardware packages that can be used in the ham shack. While the actual sending of CW, RTTY, AMTOR, and ASCII is "duck soup" for virtually any home computer, the need for an interface between the computer and the ham equipment is still a necessity. I've previously had the chance to review the original Kantronics Interface and the AEA CP-1, but I was anxious to see how the Kantronics Interface II would perform. Here are the results of my "on-line" tests.

The first thing that struck me is the size of the unit. It is small! I guess it must be my vacuum-tube background, but I always expect things that do a big job to be larger than they really are.

The next thing I noticed is that like many accessories these days, the unit does not contain or come with its own power source. I suppose this saves a few bucks and some amateurs would rather power everything off of one big twelve-volt supply. I'm not one of them.

The original Kantronics Interface, though it performed well, was sort of a minimal TU for anyone who has ever used more expensive units. The interference-rejection and signal-fading capabilities were not very good. The single bar-graph LED tuning indicator left a lot to be desired. The original was designed only for 170-Hertz-shift signals. It could be made to work on other shifts, but not very effectively. No provision was made for generating 850-Hertz-shift tones for VHF and MARS work on transmit.

The Interface II, I'm happy to say, has addressed many of these problems and conquered most of them. The unit has been completely redesigned so that it now makes full use of both the mark and space signals rather than relying on single-tone detection.

Perhaps one of the nicest features is the new tuning-indicator system. It still uses an LED bar graph, but much in the tradition of the old "magic eye" tubes of days gone by. I've used a tuning scope for RTTY and found it to be a nice luxury, but far from a necessity. With the dual-bar system used in the Kantronics Interface II, I found that tuning was just as easy and accurate as using a scope. Scope outputs are available if you still want to hook up that old tuning indicator.

The next area that I found impressive was the switch-selectable shift options. Most amateur work takes place at 170-Hertz shift, but almost none of the commercial traffic uses this shift. Units such as the AEA CP-1 allow for a variable-shift option. My experience, though, is that this is still not as convenient or accurate as having the 425- and 850-Hertz shift options switch-selectable. I'm still an old SWL at heart and enjoy tuning the press and weather transmissions. The Kantronics II is the first unit I have used that handles the commercial shifts well.

Kantronics did use one cost-saving technique for wider shifts. The same 1100-Hertz or so bandpass filter is used for both 450- and 850-Hertz modes rather than providing, say, a 550-Hertz filter for the 450-Hertz mode. This is a noticeable omission, but only slightly hampers operation at the intermediate shift.

Another nice feature is that you can hook up two different stations to the interface and select the one you want by means of a front-panel switch. This is particularly handy if you operate both an HF and VHF station using the same computer equipment.

The final new addition is an FM/AM switch. Those terms are a little misleading. Under normal conditions the TU operates in the FM mode. A small amount of audio is amplified so that it brings an op amp in the unit into hard limiting. This effectively turns over control for the signal level to the TU. Under adverse band conditions this can create a problem. In the AM mode, the hard limiter is bypassed. More audio is required to drive the unit, but you can use the audio and rf-gain controls on your receiver to more effectively control the signal going to the TU. The advantage gained can be a large one, but practice helps!

I found one major shortcoming in comparing the Interface II to the AEA CP-1. The AEA unit still seems to perform somewhat better under adverse signal conditions in the 170-Hertz mode. It also seems to permit less "garbage" through when tuning between good signals. So the choice may come down to how you feel about the availability of the commercial shifts and the switch selection between two stations. All in all, Kantronics has done an excellent job of responding to the suggestions of its customers. List price for the Kantronics Interface II is $269.95. I recommend it.

For more information, contact *Kantronics, 1202 E. 23rd Street, Lawrence KS 66044; (913)-842-7745.*

AWARDS

SCHOLARSHIP WINNERS

The Foundation for Amateur Radio is pleased to announce the 1984 winners of the fifteen scholarships which it administers.

John W. Gore Memorial Scholarship—$900: David J. Schmocker KJ9I, Oconomowoc WI.

Richard G. Chichester Memorial Scholarship—$900: Paul D. Sargis KI6U, Modesto CA.

Edwin S. Van Deusen Memorial Scholarship—$350: Timothy Wettach N2TW, Webster NY.

QCWA Silent Key Memorial Scholarships—$500 each: Bruce A. Wade N9UR, Glendale WI; Ian R. McNicholl KA9KOW, La Habra CA; Scott Smith KA2EMO, Malone NY.

Radio Club of America Scholarship—$500: Doyle B. Johnson KF6BD, Pleasant Hill CA.

Edmund B. Redington Memorial Scholarship—$500: David Swiatlowski KA2KLM, Camillus NY.

Young Ladies' Radio League Scholarship—$500: Diane E. Willemin N8CAY, Elyria OH.

Amateur Radio News Service Scholarship—$500: Marc C. Vernon KI9V, Hinsdale IL.

Columbia (MD) Amateur Radio Association Scholarship—$650: Eric J. Smith KA3KJO, Silver Spring MD.

Baltimore (MD) Amateur Radio Club Scholarship—$500: Richard A. White, Jr. KA3T, Mt. Airy MD.

Dade Radio Club Tropical Hamboree Scholarships—$500 each: Wayne F. Poole KC4XL, Surfside FL; Craig F. Rodgers WA4C, Boca Raton FL.

Lewis G. Wilkinson Memorial Scholarship—$500: David Cheitel KA2PNR, Bronx NY.

These scholarships were open to all radio amateurs meeting the qualifications and residence requirements of the various sponsors. The Foundation is a non-profit organization representing fifty clubs in Maryland, the District of Columbia, and northern Virginia. It is devoted exclusively to the scientific, literary, and educational pursuits that advance amateur radio. Information regarding the 1985 awards will appear in the spring in *73*.

VFN 50TH

A certificate is being offered by the Virginia Fone Net in commemoration of 50 years of continuous traffic-net operation on the 75-meter band, handling traffic into, through, and out of the state of Virginia. The net is non-affiliated but has a membership of 150 registered and numbered licensed amateurs. The VFN holds 2 conventions per year at various places in Virginia and all amateurs are welcomed. Membership information may be obtained from any net control or will be furnished with your certificate, if requested.

To obtain this handsome multicolored certificate, an applicant must make 2-way contact with 25 or more VFN members on any band *except during net operation*. Net time is daily on 3.947 MHz at 1600 and 1930 EST.

Send your log of information including the call of the station worked and the name and VFN number of the station worked to: Bill Redmond K4IEC, 917 Rockspring Drive, Winston Salem NC 27105. Include a summary log. Contacts will be verified from your list. Include $1.00 for handling and a #10 SASE, or $2.00 for a "flat pack" envelope. All certificates will be serial numbered and will be hand-lettered with the recipient's name and call. Contacts and requests must be made between September 30, 1984, and June 30, 1985.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 4

on 220 MHz and see if it would work here. They were absolutely disgusted when the ARRL fought them and amateurs were massively against even a no-code experiment.

I would not look for much in the way of sympathy or help from the FCC with regard to fighting off commercial demands for amateur frequencies. The hobby is no longer seen as a service, but more as entertainment for a very few technical nuts which is taking up some enormously valuable spectrum space which could be much better used.

What Will Go First

The first push is to get the 220-MHz band, which the FCC had saved from CB for the no-code ham experiment. Next look for six meters to be reallocated to something more productive for the country. Then we can expect to lose most of the microwave bands which are desperately needed for business communications. Remember that communications are going to be growing by a factor of about *one million* over the next few years. Some of this will use fiber optics, some cable, but much of it will go via microwave and satellites, and that means spectrum sacrifices.

Perhaps if the FCC had been a bit more forthright and made it clear to the League directors that the choice was between no-code on 220 or losing the band, the League might not have pushed so hard to defeat the Commission. Oh, the Commission tried to make it clear, within their legal limits, but the League was not paying attention.

From the FCC's viewpoint, amateur radio is an increasing nuisance. The hobby used to pride itself on being self-policing. Now the FCC gets complaints that it isn't monitoring and policing our bands for us. It sees a bunch of increasingly retired, lazy old men sitting around helplessly wringing their hands and bitching when other hams jam their nets and repeaters, but making no real effort themselves to solve their problems.

The FCC sees today the remnants of what was once a feisty service, one which was responsible a generation or two ago for the development of virtually every breakthrough in communications—one which greatly helped the country win WWII by providing desperately needed technically-oriented youngsters—back when the average age of hams was nearer 30 than 60.

FEMA Replaces the FCC

This year the FCC even got out of the emergency communications business by turning it over to FEMA, the Federal Emergency Management Authority. FEMA has almost no connection with amateurs, so we're losing one of the last stronghold excuses for the hobby: emergency communications. What's left in the way of rationalizations for amateurs having the use of billions of dollars worth of spectrum?

Amateur radio exists at the whim of the FCC, so why are we kicking the Commissioners in the face when they try to help us? Perhaps it is a death wish by the old-timers. Did one single amateur who fought the no-code proposition think in terms of what was good for amateur radio and for our country? Or were they thinking only of the misery they had in learning the code and which should therefore be shared by all newcomers as a rite of passage? Never mind that the newcomers aren't coming, but are telling us to shove amateur radio and Morse code up our antique antennas.

Sure, I know I'm a pariah to many hams because I stand up and tell it like I see it. That's never been popular, so I shouldn't mind when ham popularity polls put me on a level with Nixon, Watt, or Oswald. From my viewpoint, I go to great lengths to do my homework before I write. My opinions are solidly based on facts. No, the attacks are usually personal, attacking me, not what I've written. Well, how else can someone fight where the facts are against them?

What Can Be Done?

With four more years of Reagan Commissioners, if amateur radio were put on the stock market, I don't think our stock would sell. What an incredible pity, for here we are at the right time in history to provide desperately needed services to our country—and to the world. The whole world is going high-tech and here we are with one of the best training grounds for youngsters to steer them into high-tech careers—and we aren't just not doing it, no, we're doing everything we can to prevent it.

With communications about to explode, amateur radio has the opportunity as never before to invent and pioneer new communications technologies. Sadly, the hams we need to do this were shut out of the hobby, so we don't have 'em available. Luckily for the world, though not for us, Japan does have the needed technicians and engineers. They came into high-tech through Japan's no-code ham license. So we're going to have to continue to buy Japanese ham gear, two-way equipment, telephones, and so on. We no longer have the technical people to keep up with their creative designing. Soon we may not even have enough technicians to service the satellite, microwave, and fiber-optic communications equipment which is pouring into the country.

If you know of any approach which will convince youngsters that they should learn the code, let me know. I'm ready to try and get ham clubs started in every high school in America, but it is a complete waste of time even trying this without some convincing explanation for the code.

No, they won't buy that crap about Morse code getting through when all else fails. Nor will they buy it being less expensive than phone. Heck, you don't believe that old bunk any more than I do—and this in my 46th year in amateur radio. If you can give me *one* convincing reason for the code, I'll be able to get started.

FUN!

Middle Village NY 11379

CONTESTS

I'll be honest, I've never been a big contest fan. Oh, once or twice in my hamming career I've seated myself behind a microphone, intent on winning one competition or another. Unfortunately, I've never managed to do better than to win first place in the 1977 Manitoba QSO Party. Of course, I was the only New York station to participate in the Manitoba QSO Party that year, so I'm not quite sure how valuable that particular victory was.

I think I can attribute my lack of contesting enthusiasm to three factors: no antenna, no linear amplifier, and greed. Given enough money, I could easily solve the antenna and amp problems. The greed factor, however, is a bit trickier. You see, my natural avarice tends to keep me from entering contests that only offer fragments of sheepskin as prizes. A trip around the world? A 1985 Corvette? Sure. A certificate? Forget it.

Of course, the widespread cheating that goes on also turns me off. Just who regulates what goes on during these contests, anyway? Faulty IDing, the disregard of contest exchange rules, exaggerated signal reports, and just plain crummy operating practices are commonplace. Perhaps we should recruit a cadre of contest referees—hams who would be willing to tune around the bands and snitch on these creeps and cheats. Maybe then I'll be able to take contests seriously.

Anyway, for whatever it's worth, here are this month's quizzes. I feel obliged to do a column on contesting now and then, but I don't much enjoy the task.

ELEMENT 1
MULTIPLE CHOICE

1) The very first ARRL Sweepstakes was held in:
- 1) 1954
- 2) 1917
- 3) 1930
- 4) 1964

2) The very first ARRL Field Day was held in:
- 1) 1933
- 2) 1962
- 3) 1957
- 4) 1929

3) Which of the following magazines/organizations has *never* sponsored a 160-meter contest?
- 1) ARRL
- 2) *73 Magazine*
- 3) *CQ Magazine*
- 4) Quarter Century Wireless Association

4) During its heyday in the mid-1970s, approximately how many hams each year sent CW and Phone ARRL Sweepstakes logs to the League's headquarters?
1) 500
2) 1000
3) 2500
4) 10,000

5) Who is *73 Magazine's* contest editor? (No fair peeking.)
1) Robert Baker WB2GFE
2) Robert Swirsky AF2M
3) Marc Leavey WA3AJR
4) Chod Harris VP2ML

ELEMENT 2 SCRAMBLED WORDS

Unscramble these contest-related terms:

netcots	ogl	pude
plitumlire	xov	retcmopu
coclk	eky	efefoc
nananet		

ELEMENT 3 TRUE-FALSE

True False

1) In 1968, a Technician-class ham won the ARRL DX Contest. ____ ____
2) The ARRL once sponsored a contest that ran for eight months. ____ ____
3) The Helvetia Contest, held each April, is sponsored by a Swedish ham society. ____ ____
4) The ARRL once sponsored a Crossband Get-Acquainted Party to "promote fraternalism" between 15- and 20-meter operators. ____ ____
5) Most contesters use a "check sheet" to keep track of countries and/or states that still must be worked. ____ ____
6) The first ARRL VHF Sweepstakes was held in 1947. ____ ____
7) The first ARRL 10-Meter Contest was held in 1962. ____ ____
8) The first ARRL 11-Meter Contest was held in 1959. ____ ____
9) The first *73 Magazine* 75-Meter World SSB Championship was held in 1970. ____ ____
10) The winning operator in the first ARRL sweepstakes worked 20 stations in 12 sections. ____ ____

ELEMENT 4 MATCHING

Match the contests in Column A with the months in Column B.

Column A	Column B
1) County Hunters SSB Contest	A) January
2) ARRL VHF QSO Party	B) February
3) ARRL Field Day	C) March
4) *A5* International SSTV DX Contest	D) April
5) ARRL UHF Contest	E) May
6) ARRL 10-Meter Contest	F) June
7) ARRL Sweepstakes	G) July
8) Washington State QSO Party	H) August
9) *73* 40-Meter World SSB Championship	I) September
10) ARRL DX (Phone)	J) October
11) Dutch PACC Contest	K) November
	L) December

THE ANSWERS

Element 1:
1—3 In January.
2—1 In June.
3—4 Not yet, anyway.
4—3 Those were the days.
5—1 The one and only.

Element 2:
(Reading from left to right): contest, log, dupe; multiplier, vox, computer; clock, key, coffee; antenna.

Element 3:
1—False Even 1968's sunspots weren't able to provide that much help.
2—True The 1946 VHF Marathon.
3—False It's a Swiss contest.
4—False It was between 40- and 80-meter operators
5—False To keep track of stations already worked to prevent duplicate contacts.
6—True To the distress of VHF operators everywhere.
7—False Ten-meter operators had to wait until 1973 for their feelings of distress.
8—False The ARRL never held such a contest. Maybe if they had, we would still have the band.
9—False In 1982.
10—False He managed a not-so-staggering 153 stations in 43 sections.

Element 4:
1—D, 2—E, 3—F, 4—G, 5—H, 6—L, 7—K., 8—I, 9—A, 10—C, 11—B.

SCORING

Element 1:
Five points for each correct answer.
Element 2:
Two and one-half points for each word correctly unscrambled.
Element 3:
Two and one-half points for each correct answer.
Element 4:
Two points for each correct match.

How did you do?
1-20 points—Transmitting into a dummy load
21-40 points—Your elements are bent
41-60 points—A respectable performance
61-80 points—Almost a clean sweep
81-100+ points—No contest!

CONTESTS

Robert Baker WB2GFE

Atco NJ 08004

DARC CORONA 10-METER RTTY CONTEST
1100 to 1700 GMT November 3

This is the last of four tests during the year sponsored by the DARC eV to promote RTTY activity on the 10-meter band. Use the recommended portions of the 10-meter band. Each station can be contacted only once. Operating classes include single/multi-operator and SWL printer.

EXCHANGE:

RST, QSO number, name, and US state.

SCORING:

Each completed two-way RTTY QSO is worth 1 point. Multipliers include the WAE and DXCC lists, each US state, and each district in VE/VO, and VK. The final score is the total QSO points times the total multiplier.

AWARDS:

Appropriate awards to the leading stations in each classification, assuming reasonable scores.

ENTRIES:

Logs must contain name, call, and full address of participant. Also show class, time in GMT, exchange, and final score. SWLs apply the rules accordingly. Logs must be received within 30 days after the test. Send all entries to Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee, West Germany.

ARRL SWEEPSTAKES
CW
Starts: 2100 GMT November 3
Ends: 0300 GMT November 4
PHONE
Starts: 2100 GMT November 17
Ends: 0300 GMT November 18

Note that these rules were taken from last year's contest. This year's rules were not received from the ARRL in time to make the printing deadline. Check *QST* for any last-minute changes!

US and Canadian stations work other US and Canadian stations using 1.8- through 28-MHz bands, excluding 10 MHz. Operate no more than 24 of the 30 hours with on/off times noted clearly in your log. Listening time counts as operating time. Operating categories include single oper-

CALENDAR

Feb 23	73 RTTY World Championship Contest

FEEDLINE
BULLETIN OF THE CANTON AMATEUR RADIO CLUB
Affiliated with the "American Radio Relay League"

NEWSLETTER OF THE MONTH

One of ham radio's deep mysteries revealed itself to me the other day. I was sitting at my desk with hundreds of newsletters—most of them terminally dull—stacked around me, reading Canton Amateur Radio Club's *FEEDLINE*. There it was, a great truth, in a report on parade communications: ". . .a big thanks to each of you."

So what's the mystery? Just this: A newletter *is* as the club *does*. For each boring newsletter, there must be an equally boring club. In the Canton ARC, *everyone* participates! President Scott Duncan KK8D must be a really amazing fellow. And Editor Bill Parks K8JZN must have a tough time keeping up with all of the activity, yet he handles it with a flair for detail. Congratulations to Scott, Bill, and *every* member of the Canton ARC—you're doing one heck of a job!

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

ator and multi-operator with a single transmitter.

No crossmode contacts are allowed and each station can only be worked once, regardless of band. A transmitter used to contact one or more stations may not subsequently be used under any other call during the contest period (with the exception of family stations where more than one callsign is assigned by FCC/DOC). One operator may not use more than one callsign from any given location during the contest period. The use of two or more transmitters simultaneously is not allowed.

EXCHANGE:

Consecutive serial number, precedence (A if you run 150 W output or less, B if more than 150 W), your callsign, check (last two digits of the year you were first licensed), and your ARRL section.

FREQUENCIES:

CW—1800-1810, 3550-3650, 7050-7100, 14050-14100, 21050-21100, 28050-28100. Novice—3710, 7110, 21110, 28110. Phone—1855-1865, 3850-3950, 7200-7250, 14250-14300, 21300-21400, 28550-28650.

SCORING:

Count 2 points for each completed 2-way QSO. Multipliers are each ARRL section plus VE8/VY1 (74 max.). KP4, KV4/KP2, and KG4 stations are in the West Indies section, while KH6 and other US possessions in the Pacific count as the Pacific section. Final score is QSO points times the number of ARRL sections (plus VE8/VY1).

AWARDS:

Certificates to the top single-operator CW and phone scorers in both the A and B categories in each ARRL section, and the top multi-operator entry in each ARRL division.

ENTRIES:

Contest forms (log sheets, summary sheet, dupe sheet) are available from ARRL headquarters for an SASE. Official forms are recommended. Any entry claiming more than 200 QSOs must submit duplicate checking sheets. Incomplete or late entries will be classified as check logs. Logs should include date, QSO time, exchange sent/received, band, and mode. Postmark your entry for either mode by December 21. Send it to ARRL, 225 Main Street, Newington CT 06111.

Each entrant agrees to be bound by the provisions as well as the intent of the official ARRL rules, the regulations of his licensing authority, and the decisions of the ARRL Awards Committee. Usual disqualification rules apply.

DELAWARE QSO PARTY
Starts: 1700 GMT November 10
Ends: 2300 GMT November 11

Sponsored by the Delaware ARC. Stations may be worked once per band and mode for QSO and multiplier credits.

EXCHANGE:

QSO number, RS(T), and Delaware county, ARRL section, or country.

FREQUENCIES:

CW—1805, 3570, 7070, 14070, 21070, 28070. SSB—1815, 3975, 7275, 14325, 21425, 28650. Novice—3710, 7120, 21120, 28120.

SCORING:

Delaware stations score 1 point per QSO. Multiply total by the number of ARRL sections and DX countries worked. Others score 5 points per Delaware station worked. Multiply total by the number of Delaware counties worked on each band and each mode (maximum of 36 multipliers possible).

ENTRIES AND AWARDS:

Appropriate awards will be given to the top scorers. In addition, a certificate to all stations working all three Delaware counties. If you work all three counties and want the WDEL Award, send two 20-cent stamps and an address label. Mail logs by December 17 to: Charlie Sculley AE3H, 103 E. Van Buren Avenue, New Castle DE 19720. Send an SASE for a copy of the results.

EUROPEAN DX CONTEST—RTTY
Starts: 0000 GMT November 10
Ends: 2400 GMT November 11

Sponsored by the Deutscher Amateur Radio Club (DARC). Only 36 hours of operation out of the 48-hour period are permitted for single-operator stations. The 12 hours of nonoperation may be taken in not more than three periods at any time during the contest. Operating classes include: single operator allband and multi-operator single transmitter. Multi-operator single-transmitter stations are only allowed to change bands one time within a 15-minute period, except for making a new multiplier. Use all amateur bands from 3.5 through 28 MHz. A contest QSO can be established between all continents and also one's own continent. However, QSOs as well as QTC traffic with one's own country is *not allowed*! Each station can be worked only once per band.

EXCHANGE:

Exchange the usual six-digit number consisting of RST and progressive QSO number starting with 001.

SCORING:

Each QSO counts 1 point. Each QTC (given or received) counts 1 point. Multipliers will be counted according to the European and ARRL countries lists. The multiplier on 3.5 MHz may be multiplied by 4, on 7 MHz by 3, and on 14 through 28 MHz by 2. However, contacts within the same continent only count as a multiplier of one per band (including 80 and 40 meters). The final score is the sum of QSO and QTC points, times the total multiplier.

QTC TRAFFIC:

Additional point credit can be realized by making use of the QTC traffic feature. A QTC is a report of a confirmed QSO that has taken place earlier in the contest, which you send to another station. The general idea being that after a number of stations have been worked, a list of these stations can be reported back during a QSO with another station. An additional 1-point credit can be claimed for each station reported.

A QTC contains the time, call, and QSO number of the station being reported, e.g., 1300/DA1AA/134. This means that at 1300 GMT you worked DA1AA and received number 134. A QSO can be reported only once and not back to the originating station. A maximum of 10 QTCs per station is permitted. You may work the same station several times to complete this quota, but only the original contact has QSO point value. Keep a uniform list of QTCs sent. QTC 3/7 indicates that this is the 3rd series of QTCs sent and that 7 QSOs are reported.

AWARDS:

Certificates to the highest scorer in each classification in each country, reasonable score provided. Continental leaders will be honored with plaques. Certificates will also be given to stations with at least half the score of the continental leader or with at least 250,000 points. The minimum requirements for a certificate or a trophy are 100 QSOs or 10,000 points.

ENTRIES:

Violation of the rules, unsportsmanlike conduct, or taking credit for excessive duplicate contacts will be deemed sufficient cause for disqualification. The decisions of the Contest Committee are final. It is suggested that contestants use the log sheets of the DARC or equivalent. Send a large SASE to get logs and summary sheets (40 QSOs or QTCs per sheet). SWLs apply the rules accordingly. Entries should be sent no later than December 15 to: DARC DX Awards, PO Box 1328, D-895 Kaufbeuren, West Germany.

EUROPEAN COUNTRY LIST:

C31, CT1, CT2, DL, DM, EA, EA6, EI, F, FC, G, GC Guer, GC Jer, GD, GI, GM, GM Shetland, GW, HA, HB9, HB0, HV, I, IS, IT, JW Bear, JW, JX, LA, LX, LZ, M1, OE, OH, OH0, OJ0, OK, ON, OY, OZ, PA, SM, S, SV, SV Crete, SV Rhodes, SV Athos, TA1, UAs 1, 3, 4, 6, UA2, UB5, UC2, UN1, UO5, UP2, UQ2, UR2, UA Franz Josef Land, YO, YU, ZA, ZB2, 3A, 4U1, 9H1.

MONTANA QSO PARTY
1700 GMT November 10 to 0400 GMT November 11
1700 GMT November 11 to 0100 GMT November 12

Sponsored by the Yellowstone Radio Club of Billings, Montana. Work stations once per band and mode with Montana-to-Montana QSOs allowed. Work portables and mobiles as they change counties. No repeater QSOs.

EXCHANGE:

RS(T), serial number, and state, country, or Montana county.

FREQUENCIES:

Phone—1835, 3905, 7285, 14285, 21385, 28585. CW—1810, 3540, 7035, 14035, 21035, 28035.

SCORING:

Count one point for phone QSOs and two points for CW QSOs. Montana stations multiply total QSO points by number of states, countries, Canadian provinces, and Montana counties. Others multiply total QSO points by number of Montana counties worked (56 max.).

ENTRIES:

Mail logs by December 15 to Yellowstone Radio Club, 2626 Burlington, Billings MT 59102.

INTERNATIONAL OK DX CONTEST
Starts: 0000 GMT November 11
Ends: 2400 GMT November 11

Participating stations work stations of other countries according to the official DXCC country list. Contacts between stations of the same country count only for multipliers, but have no QSO point value. Each station may be worked once on each band. Use all bands, 160 through 10 meters on phone or CW. Crossband or crossmode contacts are not valid. Operating categories include: A—single operator all bands, B—single operator one band, and C—multi-operator all bands. Any station operated by a single person obtaining assistance, such as in keeping the log, monitoring other bands, tuning the transmitter, etc., is considered a multi-operator station. Club stations may work in category C (multi-op) only.

EXCHANGE:

RS(T) and 2-digit number indicating the ITU zone. Please note that ITU zones are quite different from the ARRL zones! For a list and map of the ITU zones, send 2 IRCs to the entry address listed below.

SCORING:

Each QSO counts one point, or 3 points if with an OK station. Final score is QSO points times the total number of ITU zones worked on each band.

ENTRIES:

A separate log must be kept for each band and must contain the full date. The log must contain in its heading the category of the station (A, B, C), name, callsign, address, and band(s) used. Also show the total number of contacts, QSO points, multipliers, and total score. Each log must be accompanied by the following declaration: "I hereby state that my station was operated in accordance with the rules of the contest as well as all regulations established for amateur radio in my country, and that my report is correct and true to the best of my belief."

A certificate will be awarded to the top-scoring operators in each country and each category. The 100 OK Award may be issued to stations for contacts with 100 OK stations, and an S-6-S Award or endorsements for individual bands may be issued to a station for contacts with all continents. Both awards will be issued upon a written application in the log and no QSLs are required. Logs must be postmarked no later than December 31 and sent to: The Central Radio Club, PO Box 69, 113 27 Praha 1, Czechoslovakia.

DXPEDITION TO KERMADEC

"Ron, Ron, wake up. The storm last night sank our boat! We're stuck here on Raoul Island!"

Ron Wright ZL1AMO pulled himself out of a deep sleep at 6 am to this unpleasant news. "But then I decided I couldn't do anything about the boat, so I went over to the shack and started operating."

So the unflappable DXpeditioner handled the news that his only means of transportation back to New Zealand now lay under 50 feet of shark-infested water. Operating as ZL8AMO, Ron handed out more than 10,000 CW contacts from the Kermadec Island Group, hundreds of miles north of his native New Zealand.

The Kermadec story began in 1983, when Jim Smith VK9NS contacted the New Zealand Lands and Survey Department about a joint scientific and amateur-radio expedition to Raoul Island. Jim, you will remember, led the second DXpedition to Heard Island earlier that year. Over the next few months, details of the DXpedition began to fall into place, under the guiding hand of Dr. J. L. Craig of the Zoology Department of Auckland (NZ) University.

After an exhaustive two-month search for an appropriate vessel to sail the 10-member team from Auckland to Raoul Island, both the scientific and amateur-radio teams boarded the ferroconcrete ship *Shiner* on March 13. The 18-month-old ship was registered just before sailing; this was to be its first (and last!) official voyage.

The 700-mile sail passed relatively uneventfully for the party, with some of the first-time sailors enjoying the dolphins cruising in the bow wake. The only problem was lack of wind, forcing the crew to motor almost a third of the distance. Five days later the *Shiner* dropped anchor near the loading crane, just off the northernmost (and only permanently-inhabited island) of the Kermadec Islands: Raoul.

The amateurs on the ship were in contact with the crane operator, the only amateur on Raoul, Warrick ZL8AFH. Soon the tedious and dangerous task of moving ten people, scientific gear, radio equipment, and supplies began. DXpeditioners loaded their gear into an inflatable "Zodiac" and edged closer to the sheer cliffs that mark the landing zone. Warrick swung his power crane out over the water and lowered the net to the Zodiac, which was bobbing up and down in the heavy swells. A deep sigh of relief came from scientists and amateurs alike as all equipment safely made the passage up the cliff.

Then it was time for the members of the party themselves to land. No safety net for people: just a ladder swinging on the end of the long crane. The hams grabbed at the ladder as it swung past and, hanging on tight, were whisked up the cliff, trusting to the capable hands of Warrick.

With the help of the only motorized vehicles in the Kermadecs, an old tractor and an even older truck, the five-member team permanently stationed on the island assisted the visitors to their fine accommodations. Soon the hams and scientists were comfortably installed in their quarters and ready for the serious work of the trip.

The amateur team of Ron ZL1AMO, John ZL1AAS, Roly ZL1BQD, and Duane W6REC quickly began setting up four complete stations (including an ICOM 745, ICOM 740, Kenwood TS-830, and a Kenwood TS-430). The antenna farm consisted of two tribanders and dipoles for the lower bands. The 160-meter and 80-meter dipoles were hung at the 100-foot level between towering Norfolk Pines, thanks to the climbing ability of scientist Mark Vette. Another dipole handled the 40-meter skyhook chores, as well as backing up the higher 80-meter wire.

Not long after arriving on Raoul, Ron made the first contact as ZL8AMO with N4VZ on 40 CW. Good radio propagation, especially on 10 meters, kept the QSO rate high. Everything was going swimmingly until late Wednesday night, March 21, three days after the crew landed on Raoul.

Cyclone Cyril was headed for the very exposed Raoul, so the boat captain, John Taylor, moved the *Shiner* around to the far side of the island and the most sheltered spot, Boat Cove. The three-man crew on the ship maintained hourly radio contact with the rest of the party on the island. Then, in the wee hours of the morning, the cyclone changed direction and high winds, heavy seas, and driving rain smashed into Boat Cove.

Soon the *Shiner*'s anchor began to drag, and then broke. There was nothing to prevent the ship from crashing against the rocks. All three men aboard leaped into their inflated life raft, and, thanks to a great stroke of good fortune, made it safely through the violent sea and storm to shore.

Although no lives were lost and no one was seriously injured, the boat was a total loss. While almost all the radio gear was high and dry on the island, a great deal of personal equipment and scientific gear now lay at the bottom of the Pacific. The two marine biologists took time out from chronicling new species of fish to rescue as much gear as the surf and sharks allowed. Meanwhile, Ron continued to operate, piling up more of his 10,000 CW contacts.

With their only means of transportation now gone, the party began to tune around the marine bands, looking for a ship going in the right direction. Fortunately, the *MV Vili* from Tonga was on its way south to Auckland and agreed to detour to Raoul to pick up the stranded party.

The change in plans cut the operating time short, but who knows when the next ship might have appeared. The group accepted the truncation of the operation and the additional $3000 cost and began packing their gear.

So 8-1/2 days after going on the air from Raoul, the amateurs closed down. During that time they logged more than 30,000 contacts, knocking Kermadec from 17th in *The DX Bulletin*'s Most-Wanted List right off the chart! One of the high points of the DXpedition was getting a call from BY1PK!

The amateurs left some good antennas for Warrick, so ZL8AFH could help keep the demand for ZL8 low. Warrick had a unique way of repaying this kindness.

The way off of the island was as harrowing as getting on. The gear rolled down the "Flying Fox" tram from the top of the island to the small landing platform, where Warrick stood with his trusty crane. After the gear was safely stowed aboard the landing craft, the radio operators were treated to a Raoul Island farewell: Warrick swung the hams, clinging desperately to the ladder, out over the Pacific, and dropped them straight into the water! After this ceremonial dunking, the now thoroughly-soaked hams bid good-bye and boarded the *Vili* to dry out and steam toward Auckland and home.

Ron Wright ZL1AMO

What kind of amateur turns back to the radio after hearing that his chartered ship just sank? Ron Wright says he enjoys the more relaxed pace and limited demands of a DXpedition compared to his daily job driving a taxicab in downtown Auckland. Traffic must be pretty bad if losing one's ship is more relaxing than driving!

Ron Wright ZL1AMO led four amateurs to the Kermadec Islands off New Zealand this past spring.

We can thank Ron's grandfather for his lifelong interest in ham radio. Ron first began playing with radios in high school, and in 1953 obtained his first amateur license as ZL1AMO, a call he has held for the last 31 years. During his long amateur career, Ron has remained very active, especially in contesting and DX, as well as in constructing his own gear.

Then in 1978, when his personal DXCC total stood at about 300, Ron decided the time had come to "put a little back into amateur radio in exchange for all the DXpeditions I had worked over the years." With the youngest of his 5 children well grown, Ron took some time off from guiding his taxi to join a contest DXpedition to Chatham Island, a few hundred miles east of New Zealand. While operating as ZL3HI/C in the *CQWW* CW Contest, Ron met Chuck ZL1ADI.

Pitcairn Island

Both the successful contest operation and the friendship with Chuck helped launch Ron on his DXpedition career. Their next stop was Pitcairn Island, where Ron helped meet the demand for CW contacts as VR6HI.

Transportation to and from tiny, isolated Pitcairn is always chancy. Chuck and Ron caught a freighter bound from the southern tip of New Zealand and arrived on Pitcairn a week later. After struggling up the long, steep cliff from the tiny landing area to the town, the two amateurs erected a triband, a dipole, and a vertical, and settled down to some serious radio.

Despite the mosquitos, black flies, and large, hairy spiders, the hams made plenty of contacts, relieving some of the pressure on resident amateur (and direct descendent of the colony's founder) Tom Christian VR6TC. Now the only question was how to get off Pitcairn.

The few dozen permanent residents of the island watch carefully for any passing boats (a major source of income is their trade with these ships). Whenever a ship nears Pitcairn, Tom makes contact over the radio and the islanders launch their sturdy rowboats with loads of wood carvings and postage stamps.

Ron accompanied the islanders on these trips, looking for passage off the island, hopefully toward New Zealand. The first week went by without success. Then the second week also passed without any possible arrangements. As the third week on Pitcairn rolled to an end, Ron and Chuck were beginning to wonder if they were ever going to get back to New Zealand.

Finally the *Yankee Trader*, a cruise ship which hits many of the lesser-visited Pacific islands, hove-to off Pitcairn. Yes, the captain said, he had room for exactly two people, if they didn't mind going to Tahiti.

At that point, anywhere but Pitcairn was fine with Ron and Chuck. Several days later they tried to explain to the officials in Tahiti why they had arrived without a visa. Lacking any French, it was quite some struggle, but finally both DXpeditioners were flying back to New Zealand, having made more than 33,000 contacts during their three weeks on Pitcairn.

This experience didn't discourage Ron from continuing his DXpeditioning career. Over the next few years, he operated from both North and South Cook Islands, Tonga, Western Somoa, the Solomons, Lord Howe, New Hebrides, Niue, and other spots in the region. Ron explains this wanderlust, "With my family grown, I wanted to see some of the world outside of New Zealand. With emphasis on 'seeing.' I have an eye problem that is getting steadily worse, and I wanted to hurry up and see a few things before I couldn't see them anymore."

Ron finances his own DXpeditions, saving up money from his taxi driving and sometimes leasing his cab during his longer trips. Lately he has received some help from some of the major DX foundations and radio clubs, but most of the money has come from his own pocket.

His understanding wife stays home ("She doesn't like to travel much," Ron explains) and answers the 70,000+ QSLs Ron has received from his DXpeditioning. She claims if she wasn't answering the cards, she'd be working crossword puzzles. Answering some of the cards with the wrong time or local time instead of UTC must make crossword puzzles seem like child's play.

Operating Tips

Ron's DXpedition radio is a Kenwood TS-830. He uses an Autek Research memory keyer and has recently upgraded his paddle to a Bencher model. As with most CW DXpeditioners, Ron usually operates about 25 kilohertz up from the bottom of the band: 7025, 14025, etc. Again following standard CW practice, he listens "up" about 2-3 kilohertz.

He found the pileups from Kermadec so intense that he was unable to maintain an acceptable QSO rate following normal procedures, so he resorted to some subterfuge. While continuing to say he was listening up, he actually made most of his contacts *below* his transmit frequency. "A little bit of deception, perhaps, which provided more opportunities for stations to work Kermadec," Ron justifies this unusual practice.

This illustrates the importance of one of the most fundamental operating strategies for working DX: listen for the station the DX is working, not just to the DX station itself. Chuck Coleman K6ZUR explains how he snagged ZL8AMO: "He was sending 'listen up' but I didn't hear any of the stations he was working above his transmit frequency. I tuned down below and heard one of the stations he called. I quickly zero-beat that station, gave a short call, and he came right back!"

Ron continued to work a few stations above his transmit frequency just to keep the pileup honest and to separate those DXers who were listening for the stations he was working from those with their ears glued to his transmit frequency.

Ron also likes to work down into the pileup to some extent. "The loudest stations are going to make it sooner or later, so I look for the weaker stations, the ones that might only have one chance." Let's hope not too many Big Gun DXers tore their stations apart after being beaten in the pileup by the peanut whistle down the street.

Another good way *not* to work Ron is to send your call several times. Once is enough. If you don't get through, send it once again. And don't send Ron's call; he knows who he is, and if you're in that pileup, the odds are you are calling him. (On the rare occasions that two DX stations on opposite sides of the world are trying to use the same listening frequency, you might indicate your preference.)

Ron also has little patience for the "dumb" questions which use up operating time without providing contacts. If you really want to ask him his name, location, or QSL address, wait until he's back in Auckland. "Each dumb question uses up an opportunity for someone else to work a new one," Ron explains. By the way, QSL all Ron's DXpeditions to his home call, good in any *Callbook*.

Keeping a very accurate clock is another hint toward getting a QSL card from one of Ron's DXpeditions. To save on log paper, Ron records contacts 5-10 across on his specially designed log. He notes the times for each row of contacts. In this way he fits as many as 400 contacts on a single log sheet. Obviously, if the time on your QSL card is wrong by even a few minutes, your call will be very difficult to find in that solid mass of stations.

Where will Ron be off to next? We'll have to keep our ears peeled, check the weekly DX bulletins and the local DX repeater, and practice listening to both the DX station and the station he is working, so we'll be ready for ZL1AMO's next CW DXpedition. .

Special thanks to ZL1BQD, the Northern California DX Foundation, and of course Ron Wright ZL1AMO for this column.

Listen for your loyal DX editor as T32AW from Christmas Island late October-early November. QSL via K1RH.

LETTERS

DOWN WITH CODE

As a new subscriber to *73*, I opened the magazine for the first time and ran right into your editorial message. It was surprising to find such an important and relevant message in what I thought was going to be only a technical amateur-radio magazine.

I am writing to you to express in detail my strong support for the opinions and positions you put forth in this editorial. My fear is that negative feedback from some amateurs concerning the code issue might spill over into the far more important issue you address—the importance of amateur radio as the country's main backup communication system in the case of any natural or man-made disaster up to an including nuclear war. Your concerns that amateur radio in the US may be a dying hobby, attracting few younger members, with declining strength as a market for new products or as a source of high-tech training are in my opinion true and very relevant. The current code requirements may be contributing in one way or another to all those conditions and to the detriment of the hobby; I join you in thinking that it is. But the old-timers are never going to change, and the problems may be eliminated by the upcoming computerization of code-message transmission and reception. As you point out in various articles in your magazine, with the assistance of a $350 computer and the right software, any licensed amateur operator can send and receive messages in code at speeds up to and exceeding 2000 words per minute without any personal knowledge of the code. That fact will soon allow most amateur operators to send and receive messages at a rate well beyond anyone's ability to copy manually. In an environment where it is no longer necessary to know any code to copy (even if you do you won't be able to use that knowledge in normal future QSO situations involving routine high-speed computer-assisted code transmissions), it may become even more obvious that the current code requirement is a non-productive carry-over from the past, possibly harming the hobby. Knowledge of the code is useless in the current and ever changing nature of the hobby.

Fred K. Martin
Santa Clara CA

Fred, there are a lot of active hams using code—because it is fun to use. I'm not even remotely against the code—as a fun mode of communications. My approach is purely pragmatic: We need more hams, young hams, desperately. Japan has proven beyond any argument that no-code is the answer to this one with their 1.3 million hams, so I and the FCC figured this was worth a test on 220 MHz, which is seriously underused and without a new group like this coming in will likely be lost. The ARRL led the fight opposing it, supported by ARRL clubs from coast to coast. I sure hate to see us lose 220 MHz, but it now looks like a goner, and that could start the dominoes falling, losing us the rest of the microwave spectrum. And where is communications going? Microwaves and satellites. Well, I intend to hang in there and see if I can be one of the last live amateurs, doddering into my ham shack with my walker, looking for anyone else left on 20 meters.—Wayne.

Wayne, I really enjoyed your editorials in the May, June, and July issues of *73*. I agree wholeheartedly with you that if most amateurs are against a no-code license, then these same people should be retested every two to five years to make sure they stay proficient in their code and theory.

I have yet to undersand why American hams are so uptight about having a no-code license. There are several countries, among them Great Britain, Brazil, Japan, Hong Kong, and probably others, which have some sort of no-code license and don't seem to have any problems with it. In fact, their amateur populations are growing (in some cases by leaps end bounds) while ours just trudges along. By the way, I got this information out of the "*73* International" section which I really enjoy reading.

It would seem to me that many amateurs are afraid that having a code-free license would let a lot of nuts and troublemakers into some parts of the bands. Undoubtedly they don't listen to 2-meter FM repeaters or to the 40-, 75- and 80-meter bands very often. If they did they would know that the nuts and troublemakers are already there regardless of the code requirement that is now in effect.

In closing, an interesting side note. In this month's *73* (August, '84) the results of the recent "FUN!" poll are given. In Element 2, question 16, 87% of the people polled didn't want the FCC to increase the speeds on CW exams. In response to question 24, 94% said they did not want hams to be subjected to periodic retesting. I wonder why? Could it be that they would not be able to pass the individual CW or theory tests (or both) again? They then contradict themselves in Element 3 by saying in question 35 that 70% of them can solidly copy CW at the speed at which they were licensed. Then in question 36, 72% said they could pass the theory test for their license class. If this is true, then why are 94% of them afraid of periodic retesting? Sounds very fishy to me.

Michael Friedel
Deer Park TX

Michael, a great many amateurs would much prefer to bar all further entry into the hobby in order to keep QRM down on the bands. Tests are to keep people out, not let them in. And, as you suggested, the inmates are in control of the asylum.—Wayne.

I've read *73* for years, whenever I could find it at the local newstand, but I've finally decided to subscribe. I'm not now, nor do I intend to become a ham, but I enjoy the articles and especially your editorials. Since the last time I tuned in it seems you've been doing battle with the FCC over the reason I refuse to get a license: Morse code.

Requiring someone to know Morse is somewhat like requiring a thorough knowledge of ancient Hebrew before being issued a Bible. Why bother to learn an obscure dialect when more efficient modes of communication are available? That is nonsense!

Lest someone think me a refugee from the CB-trucker mindset, let me explain. I presently work with computer-generated video—specifically, the cockpit displays in the Navy's F/A 18A Hornet fighter. This technology could easily be put to good use on the amateur bands. Can you imagine how many youngsters would become interested if they could plug the Intelevision into Dad's moonbouncer for an interactive game of real star wars?

You keep working on 'em, Wayne! I'd be Extra class tomorrow if it weren't for this "dah-dit-dah" stuff.

F. C. Glascock
Hanford CA

No, FC, I give up.—Wayne.

I have just learned something about ham radio, and after reading your May and June editorials, I am writing to tell you how right you are. I too am retired and seeking a communications medium to combat the boredom that losing daily contact with others brings.

I have only been involved in ham radio since May, and am frustrated by the difficulty encountered in acquiring information about the hobby. It's sad to see such a fine hobby suffering from a lack of publicity.

I have also developed a deep appreciation for the potential for major service by hams to our country in times of an emergency. In Connecticut, Governor Grasso was so pleased by the service hams rendered during the terrible blizzard of several years ago that she signed legislation enabling ham operators to obtain callsign license plates for only $5. Most Connecticut hams don't even know about it.

As I began reading your appraisal of the current status of the hobby, I sensed immediately that you were correct. Here I am, another old duffer joining the ranks instead of a high-school student. Certainly ham radio should be made available to them today. The various Boards of Education must take action. But, after serving three terms as our town's First Selectman, I know how very difficult it is to change ponderous democratic practices.

I am laboriously learning Morse code. As far as that is concerned, one need only listen to the bands to know that CW is obsolete and should be abandoned by hams in their licensing procedure.

Don't stop fighting for change! I already share your views, and when I get my General-class ticket I'll do whatever I can to join you in the battle. In the meantime, keep your speed up.

Norman E. Brown
Brookfield CT

73 INTERNATIONAL

Each month, 73 brings you ham-radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73: Amateur Radio's Technical Journal, *Pine Street, Peterborough NH 03458, USA, Attn: Perry Donham KK2Y.*

ANOTHER NOISE GENERATOR

Australia is about to get the German-standard stereo system, and it has caused a large amount of comment within the amateur fraternity due to both the likelihood of this system being susceptible to amateur transmissions on both 2 and 6 meters and the fear that there will also be interference to the amateur service over a large area because of the transmission frequencies of this dual-sound system's audio carriers.

The WIA (Wireless Institute of Australia) has written to the Minister of Communications in regard to this matter and a letter has been received back, but the reply is not very helpful to the amateur community.

In essence, the reply says that in the interests of making available this advance in broadcasting technique to the general public, Mr. Duffy, Minister of Communications, is asking members to accept any small inconvenience to their service which might occur in some geographical areas.

This I feel will also (when propagation is right) include areas as far away as Japan and the Pacific Ocean Islands, New Zealand, or anywhere that can receive 144-MHz and 51-MHz signals from Australia, the reason being that channel 5A, which is one of our problem TV channels down here, operates on 137-144 MHz and is used by the National Broadcasting Service.

The channel 5A vision carrier is on 138.25 MHz and the sound carrier at present is on 143.75 MHz. The second sound carrier for stereo TV will be located 5.742 MHz above the vision carrier, placing it only 7.8 kHz below our 2-meter band allocation. Going by stated deviation figures for stereo sound in the television industry, however, a deviation figure of 50 kHz can be expected, placing it into the first 100 kHz of the amateur band.

This should make all of those amateurs, both locally and internationally, who are experimenting in the 144.0-to-144.1-MHz section of the band, less than happy—to say the least.

Channel O is the other problem area as it operates on 45-52 MHz and is operated by the ABC plus NBS, catering mainly to ethnic television transmissions.

As you can see by the above, our 2- and 6-meter operations now have the potential for interference problems even without this new addition.

The Channel O first sound carrier is on 51.75 MHz, with the second sound carrier for stereo TV being located around 51.992 and deviated to (approx.) 52.042. This puts it nicely into the international 6-meter amateur band.

This latest intrusion by other services into the amateur bands could prove a greater headache, interference-wise, than the computer and VCR craze we are presently going through down here.

At the present rate of introduction into this country of rf-susceptible devices for general public use, we amateurs soon will need to have either a degree in interference engineering or very, very friendly neighbors.

VK3—150-YEAR AWARD

It is a long way back from today's celebrating of our 150 years of statehood to those first years of European settlements in the southern part of Australia.

The first purchase of land in what was to become Victoria (VK3) was made by John Batman in 1835 when he bought two million acres of land surrounding what in those days was known as Port Phillip. This land was purchased from a local aboriginal called Fudgaree for the princely sum of one dozen blankets, six dozen tobacco pipes, 150 figs of tobacco, and two bottles of rum!

John Batman marked off a site on the northern shores of Port Phillip Bay for a town that he was going to call Batmania. Luckily for us this town was eventually called Melbourne, otherwise we down here would undoubtedly have been called Batmen or Batwomen.

To celebrate our 150 years of statehood, the WIA will sponsor, from November, 1984, until April, 1985, a Victoria 150 Award Certificate.

Award Rules

Overseas amateurs have only to either contact or, in the case of SWLs, log one VK3 station to be eligible for this award. Mail claims to Victoria 150 Award, Wireless Institute of Australia, 412 Brunswick Street, Fitzroy, 3065, Victoria, Australia. You must include either a log extract of the contact or the claimant's QSL card, completed with OSO details for their VK3 contact, plus $2.00 to cover the award and postage.

The Victorian State Government is helping to print this Victoria 150 Award and has permitted amateurs to use a special "Victoria—Growing Together" logo on their QSL cards.

AX PREFIX

Our Department of Communications usually grants the use of the AX prefix for special events, such as the above. Unfortunately, it has been found that while most Australian amateurs who use the special AX prefix do the right thing by fellow amateurs, there are always the few who use these special-event callsigns for DX contacts and fail to honor any OSL obligations. Trying to remedy this situation, the WIA has requested that unless amateurs using special calls are prepared to QSL on request, they should use their VK prefix only and leave the AX to those amateurs who will QSL, thereby improving our overseas image regarding the return of QSL cards.

CW AWARDS IN BRAZIL

Brazilian CW groups are almost sure that awards are the best way to interest and develop CW operation amongst radio amateurs here. Although we have plenty of contests, it seems that freedom to operate at will and depending on available time and dates according to each one's peculiarities, awards are much more convenient to be worked than contests with all their pileups and QRM and limited time and dates.

So CW groups are doing their best to present interesting awards to hams. These are the latest three CW awards, just born for our entertainment:

CWSP YL Award—available to all radio amateurs and SWLs for proof of two-way QSOs with five Brazilian YLs, CW mode, two of them being CWSP members. Endorsement seals are available for 10, 20, or 30 YL stations from anywhere, CW mode only (YL CWSP members: PY2ATL, PY2ADI, PY2DHP, and PY2TR are always present on the BRYLA net). Do not send QSLs, but rather a certified log; fee is 10 IRCs; send to CWSP Award Manager, PO Box 15098, Sao Paulo, 01599, SP Brazil. Valid from May 1, 1984.

Coming from the CWGO group, Goias, are two new awards: *WAPP 2nd Series*—the Worked all PP-prefixed areas, 2nd Series award is available to all radio amateurs and SWLs for proof of two-way QSOs with 6 different CWGO members and 5 stations from different PP-prefixed call areas: PP1-, PP5-, PP6-, PP7-, and PP8. QSOs valid from January 1, 1984, on CW mode only.

DIB CWGO Award—the Diploma Interior Brasileiro (Brazilian Inland Award)—available to all radio amateurs and SWLs for proof of two-way QSOs, only CW mode, with all nine inland states (no ocean-bordered). QSOs valid from February 28, 1984, on. States are: PP2—Goias, PP8—Amazonas, PT2—Brasilia, Federal District, PT8—Acre, PT9—Mato Grosso do Sul, PV—Roraima, PW8—Rondonia, PY4—Minas Gerais, and PY9—Mato Grossop. PP2 Goias must be represented by six CWGO Group members. If two more CWGO members are worked, they can be used to substitute for two of the inland states.

Do not send QSLs. Logs, certified by a radio-amateur association or by two radio amateurs, are acceptable. The fee for each CWGO award is 10 IRCs. Send to CWGO Award Manager, PO Box 676, CEP, 74000, Goiania, GO Brazil.

CWGO members list: PP2-AAM, -ABE, -ABV, -ACJ, -ACK, -AEP, -AGS, -AHR, -AML, -BD, -BS, -BT, -BW, -CD, -CE, -CH, -CW, -CY, -CZ, -DN, -DO, -DV, -DX, -EHE, -EM, -FCZ, -FN, -FUT, -GHN, -INC, -JB, -JQ, -JT, -MMO, -RR, -RS, -SJ, -US, -VR, -WT, -WV, -XI, -YY, -ZI, PY3YXZ/PP2, PP2CW being the CWGO station call.

Brazilian CW groups realized that amusing-rules awards are the best way to develop radio amateurs' interest in CW operations, and so efforts are all towards this direction.

PPC Picapau Carioca (Carioca Woodpeckers Group), the oldest of CW groups in Brazil, is now coming to its 20th year having almost reached its "20 Awards Program," a sweeping and amusing program to meet all interests—with some not-so-difficult and some not-so-easy awards, and plenty of fun to amuse all and to enhance CW practice among Brazilian radio amateurs.

The just-launched *PPCMC Members and Countries Award*, joining DX countries (ARRL list) and PPC members, with a special Honor Roll Award when 200 points are reached (and a basic award at 50 points—at least 40 DX countries) seems to raise unusual interest due to the "permanent" classification list like the DXCC. QSLs are valid from January 1, 1980, so old-timers can join the fun of new hunting.

The *PPCPU Award* is presented to welcome new class-C PU prefixes. The basic award is obtained by proof of 9 PU QSOs, from PU1 to PU9; later endorsements are for the remaining 18 possible PU calls, according to suffix letters allocated to each of 27 Brazilian states and territories.

The three-class *PPC Samba Award* (South American Maritime Borders Award) is another very amusing game to be launched pretty soon, with interesting conditions and rules.

Keep an eye out for Brazilian new awards! They are fine!

CZECHOSLOVAKIA

Rudolf Karaba (OK3KFO ARC)
Komenskeho 1477
955 01 Topolcany
Czechoslovakia

CRC, PO Box 68, 113 27 Praha 1, Czechoslovakia, is offering these awards for non-European countries:

P-75-P is awarded for contacting or listening to stations in various ITU zones. There are 75 zones altogether, and three sorts of awards are available: 3rd class for contacts with 50 zones, 2nd class for contacts with 60 zones, and 1st class for contacts with 70 zones.

All contacts since January 1, 1960, irrespective of the class of operating service or the band used, are valid for the awards. It is necessary to send the applications together with 10 IRCs and QSL cards to CRC. A list of zones can be found in the *Callbook*.

S-6-S is awarded for contacts with one station on every continent on one mode. Endorsements for separate bands are available. Contacts after January 1, 1950, are valid.

It is necessary to send 5 IRCs and QSL cards to CRC.

More in my next column.

AMSAT

At the end of March, OK3DQ from Nizna nad Oravou in northwestern Slovakia started using AO-10. Jan is using a 30-Watt SSB/CW transmitter with a 21-element yagi (F9FT). His receiver has a BF981 transistor or three SK-97s, and a 2 × 10 element yagi—PA0MS. Both the an-

tennas are of vertical polarization. He is praising a busy operating service that in his bad QTH is a pleasant change in VHF/UHF. During the first two weeks of operating in mode B, he established 272 contacts (115 of them SSB) with 48 OXCC countries. By operating SSB he heard another Czechoslovak station, OK1VKP.

OK1BMW (maybe also other Czechoslovak stations) received a QSL card from W5LFL for listening to the signals from the sky!

RTTY IN CZECHOSLOVAKIA

Nearly 40 stations from Czechoslovakia are working actively on RTTY. Radio club OK1KMU is another new station. During 6 months there have been established contacts with more than 25 DXCC countries in 3 shortwave bands. In the 144-MHz band, they have had contacts with 5 stations from Czechoslovakia and 4 stations from West Germany.

IARU—REGION 1 CONFERENCE

The International Amateur Radio Union, Region 1, represents 55 national amateur-radio societies with about 250,000 licensed amateur-radio operators. Their last triannual meeting took place in April, 1984, in Cefalu, Sicily, Italy. Among the very many topics discussed, some got my particular attention.

First, the IARU proposed a new statute to its members in Regions 1, 2, and 3 which has been accepted in the meantime. Now each region will have a chance to send two representatives to the IARU Administrative Council. Together with the regulation that the office of the IARU must not necessarily be associated with the ARRL offices in the future, the new statute offers a chance to assign responsibilities and duties to an internationally more balanced group than was the case in the past. However, the ARRL has been elected again to take care of the "International Office" of the IARU.

Second, from time to time small steps towards a political union of the European Community (EC) are achieved. The latest achievement in this respect is an agreement between France and the Federal Republic of Germany that motorists need not stop and identify themselves at the border between the countries any more if they have nothing to declare.

It is only logical that the IARU, Region 1, would formulate similar goals like, for example, an international amateur-radio license. However, it will be difficult to come to such an agreement within the EC because of the sometimes very different national license regulations. I consider it rather impossible in the foreseeable future to agree on an international amateur-radio license which is honored in all countries of Region 1 because of the sometimes severe conflicts involved.

Nevertheless, some days later at the CEPT Subgroup R21 Conference in Madrid, Spain, an interesting approach to the problem was developed. It aims at a multitude of bilateral agreements which, in fact, could form a solid basis for a truly international amateur-radio license in the future.

And last, the IARU, Region 1, attempted to reduce the number of contests on all shortwave bands and formulated the following recommendations: Limit all contests to a maximum duration of 24 hours, assign only one weekend for the phone and/or CW portion of a contest, merge smaller contests into larger ones, and have only one large and one small contest per month in Region 1.

Furthermore, it was recommended to limit contest operation on 80 and 20 meters to the following band segments: 3500–3560 kHz and 14000–14060 kHz for CW and 3700–3800 kHz and 14125–14300 kHz for phone. I personally would like to see even tighter restrictions. On an annual basis, I'd like to suggest that only 5% of the number of weekends (52) times the available frequency spectrum (300 kHz on 80 meters plus 350 kHz on 20 meters in Region 1) should be available to contesters—$.05(52 \times 650) = 1590$ frequency-hours. It would then be up to the contesters how they utilize their available time. For example, they could run 2–3 full contests per year the usual way or 8–9 contests per year employing only 200 kHz of the available frequency spectrum on 80 and 20 meters and so on. Wouldn't this make sense?

The next IARU Region 1 Conference is scheduled for 1987 in the Netherlands. Then it will be the time to review the progress they—and we—have achieved in the meantime.

THE UK SCENE

The difficulties of obtaining convictions in cases of illegal use of transmitting equipment in the UK (and including the pirating of amateur bands) are eased somewhat by the provisions of the Telecommunications Act 1984, which received the Royal Assent and therefore became embodied in the law of the land in July.

To date it has been necessary for the police (we do not have an FCC equivalent) to catch offenders in the act of transmitting in order to be assured of a conviction. Just as soon as the knock came on the door, the offender would power down and so be largely immune from prosecution. The possession of equipment capable of transmitting on frequencies for which the owner was not licensed was not, in itself, a felony.

The new act conveys wide powers, both to the police and the newly-formed Radio Investigation Service (which used to be the Radio Interference Department of British Telecom), both of whom are given powers to seize equipment allegedly used for illegal transmissions. The courts may also order forfeiture of equipment without any criminal proceedings being initiated.

The act also provides new powers for the Secretary of State to "restrict the sale and possession of specified wireless telegraphy equipment" and to "carry our approval of equipment and require marking of apparatus."

The former provision raises the specter of a ban on 28-MHz linear amplifiers (similar to that imposed in the US) to prevent their use as "burners" by CB operators in the 27-MHz band. Such a ban is not likely to achieve its laudable aims, of course, since the illegal users can always find something else to occupy themselves, but it does deprive genuine users of the ability to acquire a particular facility.

The latter provision makes me wonder if the authorities ever take any notice of rules and regulations that have been previously implemented. The liberalization of British Telecom and relaxation of their monopoly included the provision that subscribers could, for the first time, buy extension and other telephone equipment from high-street stores.

In order to protect BT's network, it was decided that only equipment marked with a green dot and the word "approved" could be connected to a BT-supplied telephone outlet. Equipment not so approved must be marked with a red triangle and the words "not approved." So far so good, but if an article cannot be connected, is there any point in allowing it to be sold?

If I take a walk down London's Tottenham Court Road—the mecca for hi-fi, video, and computer enthusiasts—I can see approved and non-approved equipment side by side in the many shop windows. The non-approved equipment tends to have more facilities and be cheaper than that with the green dot. I do not think it requires too much guesswork to figure out which equipment sells the most. One can envisage a few years hence the ham shop selling a 440-Watt approved linear and a 2-kW non-approved one—quite a dilemma for the DXer!

Finally, with the Telecommunications Act 1984, the police are given some powers of arrest without a warrant in cases of illegal transmitting where a question of identity arises. I wonder if this could result in the need for hams to carry some form of ID card?

The RSGB has launched a monthly circular called *VHF/UHF Newsletter* to keep devotees of the shorter-wavelength bands fully up to date. Subscription for 12 issues is $6.00 for UK subscribers—$10.00 should be enough for any airmail costs to be covered. Enquiries to the RSGB at Alma House, Cranbourne Road, Potters Bar, Herts EN63JW, England.

This month's column is a little shorter than usual because I am rather busy with a new job. This is as General Manager of the telecommunications branch of a major airline. In addition to the thousands of data terminals worldwide, the UK telephone system, and the airport PMR and departure control systems, I have discovered I also have responsibility for a major HF station. That may well provide some interesting material for the future...

Athens 11210
Greece

Since as I'm writing this month's column we are in the middle of the summer, it is very hard to get in touch with most of my fellow SV DXers. Therefore, I have to stop for the time being introducing them, but for sure I'll come back later when everybody is back home and accessible.

These past few months we heard a new repeater that came on the air from the city of Kavalla, up in the northeast part of Greece. This one works on European Repeater Channel R7 and looks like it will be able to cover the northern part of the Aegean sea and most of the national road that connects Thessalonica with all major cities in northeast Greece up to the border with Turkey.

There is also another one that is expected to be installed very soon on the island of Kefalonia, but more news on that when it is on the air.

I would like to point out that since Greece is mostly a mountainous country, we need to have as many repeaters as we can, not only to cover the national roads and to give to amateurs in the whole country the opportunity to communicate with each other, but we need the repeaters for emergency communications—such as during earthquakes, fires, and so on.

I can assure you that we have plenty of both, especially during the summer when we have hundreds of fires in all Greek national forests. Then repeaters can prove to be very useful, as they can establish communications between city and forest departments with the assistance of radio amateurs who provide the necessary eyes for them. I'm sure that every country can take advantage of radio amateurs and their knowledge of communications, especially in times of disaster.

DUTY-FREE IMPORTS FOR INDIAN HAMS

Indian hams have something to rejoice about—import duty has been completely waived on amateur equipment. The waiver covers not only transmitters, receivers, and transceivers, but also gadgets like Morse-code readers and aural frequency readouts.

This move—license-free, duty-free import—could conjure up visions of ham shops full of amateur equipment. There is a catch to it, however. The user alone is entitled to import the equipment, so that each amateur has to import one piece of equipment and dealers cannot import for stock and sale. To be eligible for exemption from duty, the importer should obtain a license from the Wireless Adviser to the Government of India (counterpart of FCC) before the equipment is received in India.

Amateurs can join together and import equipment under a joint bill of lading or can give a letter of authority to a dealer who then can import a consolidated shipment as their agent. One dealer, VU2TP, agent for Yaesu, tried to put together a group of over 75 for the FT-77 at a discount of over 20% over the normal rate. He enrolled over 100, but could never quite make it. Enter the 757GX, and the FT-77 group dwindled to well below 75. Back to square one!

Now is the time for anyone wishing to send gifts of new or used equipment to Indian amateurs. Here is the checklist:

- Notify your donee that you propose to give him equipment as a gift.
- Enclose a catalog page, preferably showing the price. The amount of the price is immaterial—he can receive up to US$870 in a fiscal year (April to March) and does not have to pay a cent of duty.
- If no price is listed, obtain a quotation from your local friendly dealer or make a copy of any classified ad to establish a price (any price!). If you are offering home-

brew equipment, enclose a declaration that it was homemade and that it cost you so many dollars.

- Wait till the donee confirms that he has the WPC license for this specific piece of equipment. *Only then can he import it duty-free.*
- Ship it by any mode; surface mail, air mail, air cargo, or even sea cargo, but *not* as passenger baggage. Ham equipment as baggage *is not eligible* for duty-free entry.
- Send the bill of lading to the donee by air mail. If sent by air cargo, QSP to him the particulars of the bill of lading or send him a cable. Demurrage on air cargo is quite heavy and could add up to a hundred dollars in eight weeks.
- Do not ship by air cargo to donees who are not in the cities of Bombay, Delhi, Calcutta, Madras, or Bangalore. Others will have to make arrangements at one of the entry points to file a bill of entry and to clear the parcel through customs.

The Indian amateur can import components, too, but only as spares for equipment that he imports. Obviously, this bit has been influenced by commercial interests—the home-brewer still has to pay duty if he wants components. Strange situation, but one learns to take these in one's stride. The Federation of Amateur Radio Societies has made representations that the home-brewers' imports of components (not spares) should also be exempt from duty. Let's keep our fingers crossed!

Here is the full list of equipment and components that are exempt from import duty:

Wireless Apparatus and Accessories

1. HF transreceiver (transceiver) meant for amateur frequency(ies) with accessories.
2. VHF transreceiver meant for amateur frequency(ies) with accessories.
3. UHF transreceiver meant for amateur frequency(ies) with accessories.
4. VHF/VHF or VHF/UHF repeater (combination of transmitter and receiver) with accessories meant for amateur frequencies.
5. Control unit for the 4 items above with accessories.
6. Aural readout displayed frequency.
7. Aural readout displayed time.
8. Aerial/antenna for amateur frequencies.
9. Balun transformer.
10. Swr bridge or reflectometer.
11. Digital frequency counter (up to 600 MHz) with accessories.
12. Morse reader.
13. Noise bridge.
14. Microphone (with or without loudspeaker).

Components

1. Transistors, diodes, integrated circuits/chips.
2. Thermionic valves or vacuum tubes.
3. Toroidal cores.
4. Quartz crystals.
5. Variable condensers, air-dielectric type.
6. Precision capacitors (fixed type), value(s) between 1 pF and 5000 pF.
7. Relays.
8. Rf cables.
9. Spare nicad cells or pack as required or used with items 2 and 3 above (in case of hand-held transceivers).
10. Rotary switches.
11. Keyer paddle.
12. Ferrite beads.

18 AND 24 MHZ

It is a few months now that 18 and 24 MHz have been used by Italian hams, but there is not too much activity. If you open your rig there you will only find QRM. The reason could be the fact that no Ws or JAs are allowed there, but maybe there is another reason. The fact that both bands, by IARU decision, are not used during contests and are not valid for any award probably keeps us off them. The reason for the IARU decision was justified by the need for not having all of us there together, but it seems they have obtained the opposite result: nobody is there. The cost of antennas with practically no return in terms of what is wanted by DXers (contests and awards) is too high. According to old-timers, this happened also to 21 MHz years ago, so probably it is not necessary to worry too much; we're waiting for our friends from Japan and the States to come and give some life to the two new bands.

UHF SHF

Years ago the I2X beacon was installed in Milan, operating with 40 mW on 10 GHz. The results have been very good; the beacon was well received within a range of 250 kilometers, with mostly late-evening openings. During the month of July, IØSNY of the 10-GHz world record will be back in North Africa trying to set new records, working 24, 10, and 1.2 GHz, and offering the possibility to have a new one to many Europeans on 144 and 432 from EA9.

DINO ISLAND EXPEDITION

Dino Island is located in Calabria very close to the coast. (This answers all those that have asked for it as, being very small, it is not on normal maps.) It is very easily reached with a small boat and is populated only during the summer by tourists living in a small village.

The island was activated for the first time in June, 1983, with the call ID8UDB, a new prefix and a new IOTA number. It was activated mainly on CW (95% of the total QSOs) by three operators of INORC (Italian Naval Old Rhythmers Club) and the DX Blue Team: I2BVS Enzo, I2DMK Max, and I2NYN, his son, Marco.

The operation started on June 7 and ended June 14 with 5600 contacts, most of them on 14-MHz CW, as the propagation was quite poor. The antennas used were a two-element beam for 10, 15, and 20 meters installed on top of a 10-meter portable tower of only 8 kilos, and a ground plane for 80–10 meters.

The ground plane was not working too well on 40 meters and a new antenna was installed, coupling a 12-meter longwire to the metal tower. The sloper so obtained was working perfectly, giving satisfaction in working many USA, JA, and VK stations on 40. As said above, 20 meters has been quite good while 15 has been very lousy. 10 meters has been offering short-skip openings to Europe and some sporadic-E to South America. QSL cards via I2MQP.

9X5GB

If you have the opportunity to work the above callsign (it is not yet official as the station has been working up to now with the call I2XDP/9X5), you will realize, upon receiving the QSL card, that it is not a normal station. It is the station of the hospital run by Italian missionaries in Musha and, on top of it, it's working with the power of solar panels that are linked to two batteries of 12 V, 66 Amps. The rig is an FYT-707 and the antenna is a 3-element by Hy-Gain.

Other solar panels are linked to batteries that are used to serve all the mission. Of course the strength of the sun in Rwanda must be consistent to do such a beautiful job, but the Black Continent and Italian ingenuity can offer you more surprises—like the 5H3KG station (another well-known call run by another Italian missionary) that is powered by the wind. I will offer you more news on it in a future column.

WORKING THE LOW BANDS

Due to the actual slowdown of sunspot numbers and thanks to the new life given to the low bands, a new antenna is becoming popular in Italy. It's the DB24, the 4-element by Hy-Gain, with two active elements on 40 and two on 20. The price is quite attractive, being about $180 while you have to pay more than $650 for a TH7DXX. So, if you find many more stations during the next contest season working on 40 from Italy, you can bet that many of them are using it.

Always staying on the low bands, a modification to the well-known W3DZZ has been offered in the July issue of the Italian amateurs' magazine by IØNQT, allowing the popular dipole to work on 160 meters. Two traps have been added with 33 feet of wire. The antenna is working very well.

The first contact between Italy and Australia has been made by I2BBJ and VK6HD on April 25. The contact was made feeding the 30-meter tower you can see in the photo.

Republic of Liberia

AMATEUR RADIO IN LIBERIA

The Ministry of Post and Telecommunications called a meeting of all the amateurs in Liberia. It was called in conjunc-

Dino Island.

The I2BBJ end of the VK6HD-Italy contact.

tion with the Liberia Radio Amateur Association (which did put out an agenda), but the object of the Minister's interest in the meeting was not given. The Ministry expressed a degree of urgency in their notices to the amateurs to attend the meeting and implied that absence without good reason would not be taken lightly.

The amateurs came into Monrovia by air, by private automobile, by taxi, and by whatever mode of travel was available, and the meeting was the best attended and the most successful that I have seen in my three and a half years in Liberia. As the assembly gathered, there was tension in the air and everyone walked around with a feeling of apprehension. As it worked out, this apprehensive feeling proved to have been unfounded, however; this meeting was some kind of a first and no one knew just what to expect.

The Minister—actually the Assistant Minister in charge of radio operations—opened the meeting. One could have heard a pin drop. Sensing the tension, the Minister did what he could to make everyone feel more relaxed and comfortable. He welcomed those present and expressed satisfaction at the number who had responded to his call. A roll call indicated that upwards of ninety percent of the amateurs of Liberia were in attendance. Those who were not present were either out of the country on leave or at work in a position that did not permit absence.

The Minister did not keep the group waiting. He stated simply and briefly that a problem was developing in Liberia in the area of third-party traffic and other markedly commercial (and therefore illegal) communications in the amateur bands. He said that complaints were coming in from countries outside. He pointed out that for many years Liberia has enjoyed an enviable reputation in the world of amateur radio for its courtesy and its observance of national and international law, and he said that the Ministry and the amateur community of Liberia is very jealous of this reputation and will preserve it.

He was quick to mention that the problem is not widespread. The aim of the Ministry is to see to it that the problem does not grow. He asked the cooperation of the amateurs to eliminate the problem completely.

I have noted in other columns that I have sent to *73* that I have been greatly edified by the caliber of courtesy and the observance of amateur regulations here in Liberia. I have a hunch that these few problem-amateurs are expatriates. If this is true, it is unfortunate because the Ministry of Post and Telecommunications has been most generous in licensing people who are not citizens of the country. As an instructor in amateur radio and as a member of the examination committee, I have been working rather closely with the Ministry and there is not a single instance, in my experience, in which a foreigner, of whatever race, has been denied a license when he has completed the requirements in code and theory.

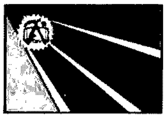
This is not true in all countries. I personally was denied a license in another country where I was working for eight years simply because I was not a native. At least that is the reason that was given. We, who are visitors in Liberia, would do well to cooperate with the Ministry and observe the law.

The Minister spent the greater part of the meeting encouraging the amateurs to be more active, to participate in the local nets, and to join the Liberia Radio Amateur Association. He suggested that the amateurs use the facilities of the Association to handle QSL cards, going and coming, and to work with the Association in instructing and training new amateurs. He recommended that local areas organize clubs or associations so as to coordinate their efforts to manage and develop the amateur community in Liberia.

In the meantime, the Association is working on a program for Amateur Radio Week. It will be held in the latter part of November or the first part of December, and while things are in no way finalized, it is fairly certain that there will be a special callsign for that period. There will be a special-event station and there may be awards. Turn your dial, look for Liberia, and take full advantage of this opportunity! There will be publicity. Be on the alert and don't miss it.

The Association again petitioned the Ministry for a spot in the broadcast band to transmit code for practicing beginners. The proposal was well received and it may well be that, one of these days, there will be something to report in this area.

We, the amateurs of Liberia, look forward with confidence and hope. We are sure that we will continue to grow in strength and prestige as we hold our place among the amateurs of the world.



MOZAMBIQUE

Charles E. Martin AB4Y
American Embassy Maputo
Department of State
Washington DC 20520

Greetings from Maputo (old name: Lourenco Marques) by the beautiful Indian Ocean. No, fellows I don't have a license yet. As of this writing, amateur radio is "suspended" in the People's Republic of Mozambique. I am a foreign service officer, and in the diplomatic lexicon "suspended" is better by far than "prohibited" or "cancelled." If an activity is "suspended," then the authority is stating that the condition is temporary. I still remain very optimistic that amateur radio will return to Mozambique.

Mozambique has a full share of the typical third-world nation's problems. It is one of the most miserably poor nations on Earth. In 1983, 100,000 people starved to death. (Your tax dollars are supporting the largest aid program on Earth to get food to the people here.) Three out of five Mozambicans cannot read or write. Virtually all the technicians in the country are foreigners from Europe or the communist bloc.

The main reason for the absence of amateur radio is the fact that the country is undergoing a massive guerrilla insurgency. This city of 850,000 people is virtually cut off from the outside world as far as overland travel is concerned. Add that to the government's general paranoia and distrust of foreigners, and it is apparent that amateur radio is not at all welcome under the current security situation.

My wife Yee's (N4GPB) and my chief concern is food. The currency here is virtually worthless. The official exchange rate is 40 per US dollar, but the free-market rate is 1500. The currency cannot be converted at the official rate. The stores have no food and the restaurants serve only a rice-water gruel. When the road to South Africa is open, it is a 5-hour drive to the grocery store. Now that the road is closed, we have to get our foodstuffs shipped in and rely on the "hard" currency shop here in Maputo.

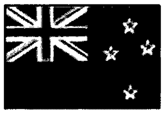
As far as ham radio goes, I am occupying my time by teaching ham radio to four other Americans and modifying my gear to run on 220 V, 50 Hz. My house servant plugged my 24-hour digital clock into the 220-V current and blew it up. It cost more than he earns in three months. Most Mozambicans earn less than the cost of a 2-meter transceiver in a year.

My house was built before electricity and the wiring is adequate, but nothing fancy. I am getting additional outlets and transformers installed in my radio room. We get television from ZS and 3D6 here, so the city is filled with towers and antennas. I am getting a 60-foot tower installed and I will hang my tribander on it. I have been monitoring the bands and have heard many US stations on 20m, but I have not heard any amateur stations on 30m here yet.

I have been doing preliminary research into the possibility of running a DXpedition to some of the offshore islands. The French have a large embassy here, and I can easily arrange transport to Europa and Juan de Nova islands. The western diplomatic community here is very close, and arranging the landing permits and operating permission should present no real problem.

I will remain in Mozambique for at least two years, perhaps until 1988. I am hopeful that I will receive operating permission before I depart. Mozambique is a difficult and uncomfortable place to live, and amateur radio would make it much more pleasant. I am planning to visit several of the nearby countries during my stay here, and I plan to operate from several of them.

I have never run a DXpedition before, so if any *73* readers could offer assistance in DXpeditioning, I would be most grateful. Unfortunately, there is no "handbook."



NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

This month I shall continue the New Zealand offshore islands' stories with an excerpt from the Raoul Island expedition story, through the courtesy of the author, Roly Runciman ZL1BQD, and *Break-In*, the NZART Official Journal. As reported in my July column, the Raoul Island DXpedition took place in the second half of March this year and was successful from the radio and scientific points of view, but a disaster for the owner of the yacht *Shiner* used to transport the expedition to the Kermadec Islands.

Departure: Tuesday, March 13, 1984, at 11:30 am NZT, the group was aboard the yacht *Shiner* on their way to one of life's great adventures. Years of hard work by Ron ZL1AMO and months of departmental negotiations by Dr. John Craig, the leader of the scientific party, had finally paid off and they were on their way to the Kermadec Group of Islands, destination Raoul Island, ETA 5 days.

The Travelling Party: There were ten persons on board, five in the scientific party, four in the amateur party, and the Captain, John Taylor. The scientific party consisted of Dr. John Craig, expedition leader, who was to study both the native Kiore rat and the introduced Norwegian rat populations on the island; Anne Stewart, to study the native Tui bird population and compare their song and other characteristics with the New Zealand native Tui bird; Mark Vette, a great climber of trees, which was very much appreciated when antennae went up and down, whose main job was assisting both John and Anne in their studies (Mark is by trade a very capable scientist in animal behavior patterns); Dr. David Schiel, a marine biologist and an extremely good diver (he assisted when disaster struck the yacht); and Mike Kingsford, another marine biologist studying fish life and migration patterns from the northern Pacific down to New Zealand. For his investigations, Raoul Island is a very handy "half-way house" for the migration patterns.

The amateur-radio party consisted of Ron Wright ZL1AMO/ZL8AMO (and many other DX calls—the CW expert who worked approximately 10,000 QSOs); John Litten ZL1AAS/ZL8AAS, who mainly operated phone and stacked up about 5000 QSOs; Roly Runciman ZL1BQD/ZL8BQD, who operated both phone and CW on all bands, also working 10,000 QSOs; and Duane Ausherman W6REC/ZL0ADW/ZL0ADW/8, who operated both SSB and CW with slightly more emphasis on CW and did very well with 5000 QSOs for his first DXpedition.

Journey to Raoul: The journey-to-Raoul routine consisted of three hours on watch and six hours off for the five days. Time is measured by daylight and darkness rather than by the days of the week—every three hours another shift comes on and the one going off gets a quick bite to eat and then tumbles into bed.

One of the amazing occurrences during the voyage was seeing the small "Welcome Swallows" along with other bird life with land two or three hundred miles away in either direction. The scientific experts when asked, "Where do they go at night?", replied, "Oh, back home again; they can fly enormous distances, and they will be back here again tomorrow!" Then there were the dolphins riding our bow wave. . . and the spectacular sight of seeing the seas burst into green light with phosphorescence during the small hours of the morning watch. And there were the moths and butterflies three hundred miles from land; where do they come from?

Every hour the travelling log is read and entered into the ship's log, and every day we call up Auckland Radio and "home" to give positional reports and get the latest weather information.

After four days of nothing we sight the first island of the Kermadec Group, Esperance Rock. Later that day we passed between the next group of islands, Curtis Island, which is still an active volcano with quite a bit of steam escaping from the crater, and Cheesman Island, with an extinct volcano, covered with quite bushy vegetation and inhabited by bird life. Soon radio contact was made with Warrick ZL8AFH via Marine Channel 16, and we are told to lay off as close to the landing platform as we like. The great moment is at hand; we have arrived at Raoul Island!

Landing: Landing at Raoul is a very delicate task. There is no jetty or wharf. Goods and chattels have to be landed by being lifted from small boat to the landing platform by a manually operated crane using a cargo net. Mere humans have to clutch a ladder attached to the crane hook and hope that the crane operator knows what he's doing in the winch house! Judging the position of the ladder relative to the swells is quite a feat.

The small landing boat, *Chunder [Ed.—A down-under word meaning throw up]*, is well named and it, along with everything else, makes the journey up the cliff from the landing platform, "the flying fox," hauled by yet another manually operated winch, quite exciting.

Once at the top, there is conclusive proof that we are indeed on Raoul Island,

for we are confronted with a large notice with instructions "to prevent damage to the vegetation and the natural features of the island."

Our Temporary QTH: Raoul Island is quite a paradise in the South Pacific. It is still an active volcano with upwards of six earthquakes per day, most not felt by those on the island, though one or two heavier jolts reminded us of the continued activity. Most of the island is covered in Nikau palms as a type of undergrowth, with a canopy of beautiful Pohutukawa trees overhead. Along the northern coastline is a self-sufficient farm which supports the permanent residents on the island. The coastline is extremely rugged, with only a very small rocky beach along the western coast where the original settlers, the Bell family, used to live many years ago. There are still a few goats and many wild cats on the island, and, of course, lots of rats. Bird life is quite prevalent, with the song of the Tui making the bush come alive. The oranges from the orange grove have to be tasted to be believed, and delicious bananas grow freely as well.

The personnel on the island are a terrific band of fellows, and they treated the expeditioners very well during their stay, especially when the tragedy with the yacht occurred a few days after arrival. Mike (the officer in charge) took care of the landing formalities, passports, etc., and settled us into our quarters; Paul (Lands and Survey Department) was our island tour guide and was a tower of strength; Garth (Met Office) was the Raoul Island champion table-tennis player, who was deposed by Roly ZL8BQD. Garth is also the photographic expert in the group. Tom is the resident mechanic and an expert cook into the bargain; and Warrick ZL8AFH was the technician and radio operator. When the amateur DXpedition left the island, they left Warrick a triband beam and various assortments of wire and coax, so his signals on the higher frequencies should be better than they were before.

The Amateur DXpedition: Radio operation was the amateur highlight of the trip and, of course, one of the reasons for the expedition. Some 30,000 QSOs were made with all points of the globe, propagation being good on all bands at some time every day. Antennas were a 160/80m dipole, up about 80 feet between two very high Norfolk Pine trees, and two triband beams. Equipment used were the ICOM IC-745, IC-740, ICOM Auto Tuners, and the Kenwood TS-830 and TS-430.

The DXpedition again tried to cater to as many facets of the hobby as possible, especially QRP operation. For those stateside stations who stood by to enable the DXpedition to do this, they extend their grateful thanks. The best QRP was with N6HJ with 100 milliwatts, believe it or not, and many stateside stations gave the report, "I don't know how QRP I am, but nothing is moving here!" Great stuff fellows, hope we can do it again sometime from other Pacific DX locations.

One QSO that made a nice change was being called by BY1PK, an unusual switch that was appreciated by all. Also the operators would like to make special mention of Werner DM9KE and his net on 21.157 MHz; thanks Werner for getting so many of the Europeans through to make those valuable ZL8 QSOs.

Disaster Strikes: Life was quite exotic until March 21, three days into the operation, when Cyclone Cyril made its way down from Tonga and struck the island in the small hours of the morning amidst driving rain, total darkness, and driving seas. At 12:15 am the anchor ropes holding our yacht, *Shiner*, broke and allowed the boat to hole itself against the rocks in Boat Cove. Our Captain, John Taylor, and two of the scientists were on board at the time and had to abandon ship into their Avon landing craft amidst all the elements. They made their way to shore to a landing over very large and dangerous rocks. All they had to guide them was the light of two torches held by the shore party to show them a "channel." They were indeed fortunate to catch the right wave and surf over the rocks to make a scrambled, but safe, landing.

We were indeed fortunate no lives were lost. The boat was a total loss, including quite a bit of personal gear on board. Our hosts on the island together with the oceanographers from the scientific party did a terrific job salvaging what was possible from the wreck over the next two days. A bit of a damper to the expedition, but when it was known that no lives were lost, the radio operation could at least carry on with easier minds. Of course, they now had to find a way to make alternative arrangements for the trip back to New Zealand. After several different alternatives, they finally had to accept the offer of a diversion pick-up by the coastal freighter *MV Vila* en route from Tonga to Auckland. The cost of the diversion was $3,000, an added expense they had not counted on, but there was no choice.

So, after an uneventful trip home, apart from a little seasickness, the expeditioners arrived back in Auckland for a reunion with their families; so ended the trip of a lifetime to the rare and exotic Kermadec Islands.

BITS 'N' PIECES

One of the chores the members of the Kermadec expedition told us about was the baking of their own bread and the trouble they had keeping track of which loaves were the fresh ones. Amateur ingenuity and some food dye came through with the answer—color-coded bread, a great idea so long as someone remembered the color coding.

More 6m VHP news from Terry ZL2TPY indicated that April provided more surprises with every type of propagation taking place during the month: sporadic-E, F2, TEP (Class 1 and 2), Backscatter, and tropo, etc. His running total of 6m QSOs for the last four and half months has well passed the 1000 mark (nothing under 160 kms) with over 600 plus stations worked. The overseas DX within the Pacific Basin and the States continues with this month's total bringing up his total of call areas worked to 39 for the same period. The JA totals for the past summer season to April was 440 JAs, all 10 Districts, and 54 JA prefixes, so 6 was very much alive in the early part of this year.

Old-Timers Club news for the month included a 50-year Certificate to Honorary Member Mrs. Austine Henry VK3YL and 60-year Certificates to Frank Bell ZL4AA (ZL's first amateur) and Bern Spackman ZL1GV, ex Z2BM. Silent Keys recorded were Morrie Walker ZL1AU, ex ZL3FQ, Wally Wainwright ZL2IS, ex ZL2IE, and Clinton Way, ex ZL2JC, and Sydney Carpenter.

OTC Awards made at the annual meeting of the Club held during the NZART Conference recently were to Arthur Allen ZL1JQ, who is the Grand Old Man (President) for the 1984/85 year, and the Montgomery Cup, for the best contribution to *Break-In*, went to George Anderson ZL2JG, for his several contributions to *Break-In* during the past year.

NORWAY

Bjorn-Hugo Ark LA5YJ
N-3120 Andebu
Norway

Here we are again. I sincerely hope you all have had a pleasant vacation, nice weather, etc. I have had the pleasure to be able to join in on a couple of ham meetings, and I will today take you to the biggest ham festival in Europe, The HAM-84, at Friedrichshafen, southern Germany (or "Bodensee Treffen," which it's also called since Friedrichshafen lies on the shore of the Bodensee, facing the Swiss border).

We were three ham operators taking the ferry from Oslo to Kiel in northern Germany, and we drove the 1000 kms south to Friedrichshafen in one day. Henry LA3FI, the owner of Norsk Radio Supply, took care of the driving and Brynjar LA1AR and I took care of the mapping and sign reading. We never left the Autobahn except for refilling the car and the stomachs. LA3FI's Mercedes never got below the 100-km/h mark, and very often it was closer to 200 km/h. Certainly we did not see much of the landscape.

We came down to Friedrichshafen and had quite some problems in getting lodging, but managed after a while to get booked in at a couple of small hotels. Remember, when traveling in Germany, to take your own soap with you if you want to shower. We didn't remember, but a little organizing worked that out.

The very next day we had the pleasure to see the biggest and nicest place for a ham operator to see. Gee, man, even we who work in the business were amazed. And the flea market overflowed with all kinds of surplus and used gear. We spent some good times chatting with exhibitors from all over the world. We did have the great pleasure to meet Mr. Bob Cushman from the Cushcraft company and spent quite some time chatting about antennas. A very pleasant meeting indeed, both personally and business-wise.

Other exhibitors included, of course, Telex-Hy-Gain, and we did have a couple of nice chats there, too. There's only one drawback in dealing with US companies these days, the US dollar is so extremely expensive at this time. During the last six months it has gone up 16 percent, and that is very hard on amateurs. Raw materials have been raised 20 percent, and it's really a killer for business. But anyhow, we did enjoy the whole exhibition.

Later that evening we had the pleasure to join the ham party and had a very nice chat with Kurt HB9MX and Baldur DJ6SI. The latter is a very famous DXpeditioner who you certainly have worked from a few of those far-off rare DX countries.

We also met Bjorn SM6EHY, who immediately got fired up on low-band DXing. I will write about Bjorn in a later column. One thing that really surprised me was the generally friendly attitude shown by everyone to everyone. It was just a great pleasure to be a foreign visitor. As a DXer, I certainly got interested in the DARC's DX

The DARC's DX stand. In the middle are Herb DL2DN and Harry DL8CM.

73 INTERNATIONAL

from page 94

stand and had nice chats with a few of the guys behind the stand.

We did, of course, take the opportunity to use the hospitality given by the combined representatives from the Post and Telegraph services in Austria, Switzerland, Lichtenstein, and Germany, who on the spot issued visiting licenses on a reciprocal basis without any fees at all. I personally had the opportunity to obtain LA5YJ/HB, LA5YJ/HB0, DL/LA5YJ, and the tongue-breaking OE1XFB/LA5YJ. Only the French representative was missing, and we were missing him.

As you may have gathered already, we did take a trip through Austria, Lichtenstein, Switzerland, France, and Germany, but unfortunately we did only bring a 2m FM rig this time, and I had the pleasure of chatting with amateurs from all of these QTHs except from France, where we couldn't obtain a license on such short notice. The only thing that took some pleasure off the trip was the weather. Maybe someone disliked the kind of rf I was transmitting through the air! It was raining like I have seen only in the tropics, and I'm sure that part of the world got enough rain to put the Sahara Desert under water during that day.

Everyone assured us that this was very unusual; normally the weather should be nice and sunny this time of the year. However, next time we're going to bring with us an HF rig and spend some time in each of the countries trying to create a few pileups. I'm sure the weather will be much better then. I will say that if you get the opportunity to go to Europe during the last part of June next year, take the chance and join in on the Bodensee-treffen 1985. You surely won't regret it. If interested, write to DARC-Deutscher Amateur-Radio Club e.V., 3507 Baunatal, Lindenalle 6, Germany. The affair is absolutely one of the best I have attended, and remember, it's only for ham radio.

BJARNE ERIKSEN LA4HF

I would like to present to you another DXer from Norway, one of those you never hear too much from or about, which does not mean that he is not one of the big ones. Just the contrary. Depending on what you consider as a "Big Gun"—one with a big antenna farm, big equipment, or the capability to get the rare ones—Bjarne P. Eriksen LA4HF, from Likollen, near Oslo, belongs to the last category. He was born in the southern part of northern Norway in 1928, and will soon be 56. He was first licensed in 1955 and was really bit by the bug when he worked his first real rare one in 1958, VK0TC, on 15-meter AM. Since then it seems that his interest in DXing has just increased, though it has never taken control over his life and work.

Bjarne lives with his wife, Liv, in a one-story house in a suburb of Oslo. Around 20 km from the inner city, nothing except the 12-meter-high tower with a Classic 33 from Mosley can pick him out as being any different from all the other people living around there. He also has a multiband trap dipole for local 80- and 40-meter work, since he never has taken any interest in low-band DXing.

His equipment has been for many years a Yaesu FT-500, but last year he realized that the rig was starting to get a bit too old, and he traded it in for a brand new Yaesu rig, the FT-980 CAT. You can imagine his happiness about this rig. Even though he thought quite well about the old one, which had served him well for so many years, his answer to my question the other night, if he would like to switch back was rather short and precise: No way! And you know, the new toy got the flame burning a little higher. He is really sincere about his hobby, and it relaxes him from his work as a Managing Director at E. Stephesen AS, in Oslo—a firm specializing in hearing aids.

When I was visiting him I tried hard to move him into buying a new tower and a bigger antenna, but he was concerned about his neighbors. The idea is not new to him, however; I think time will tell!

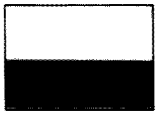
Bjarne has managed to work 304/318 and is still waiting to work such easy goodies as 4U1UN, ZL/Chatham, XF4, and BY. I know that Bjarne would be very happy if anyone working from those locations could give him a hint about when they will be active. In addition to his FT-980, he has an SB-230 linear, Amtor MkII from ICS electronics, and a BBC model B computer.

LA4HF has other interests as well. He loves traveling and is starting to be a little globe-trotter. He has been visiting HS, CN, 3V8, SV5, and 5Z4 and is planning to pay a longer visit to HB9 this summer. He also is very interested in salt-water fishing and is very happy to pull up a couple of big cod.

Bjarne is very happy to spend time chatting with people and does not mind ragchewing at all, but a new one gets him always on the tense side, so to speak. Understandable, and I sincerely wish him luck towards the DXCC Honor Roll, where I, personally, think he belongs.

In another column I will present to you Bjorn SM6EHY of Sweden and another ham meeting we have been to.

Take good care, my friends; see you soon.



POLAND

Jerzy Szymczak

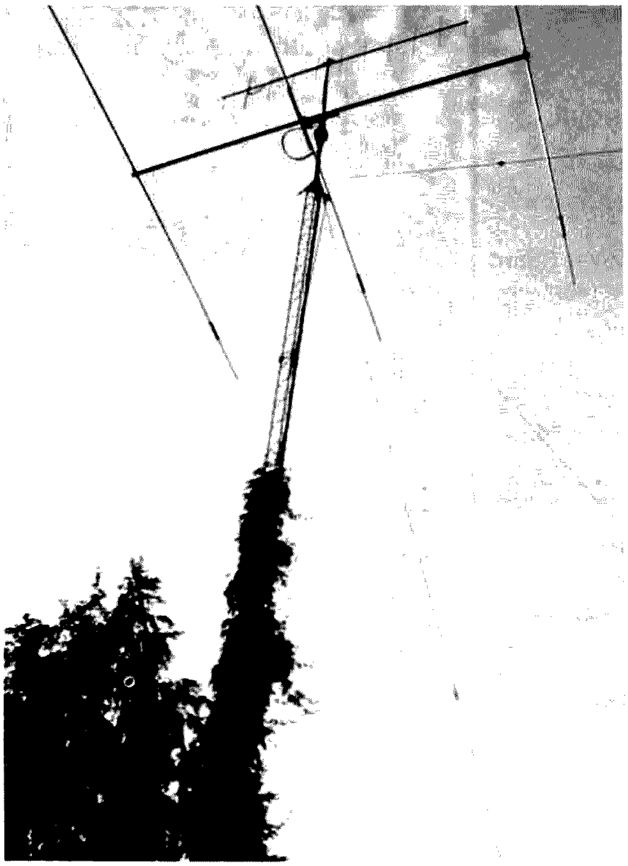
Buczka 2/3
Poland

On January 28, 1984, the plenary session of Headquarters of PRAA (Polish Radio Amateurs Association) took place in Warsaw. Important resolutions that will exert an influence on the future activity of Polish hams were adopted. The PRAA electoral campaign began in February. Elections of delegates to district conventions were to take place at electoral meetings of radio-amateur clubs from February 1 to March 31. The district conventions elect deputies to the National Congress of PRAA in October or November. All



LA4HF's antenna farm. The wild climbing plant adds an unusual touch.

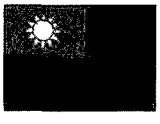
holders of valid licenses may have a share in the district conventions as ordinary members; on the other hand, persons who are bringing their licenses up to date may take part in them as "extraordinary members" if they are elected by a club. One deputy to the National Congress is to be elected for every 20 ordinary delegates to district conventions. Candidates elected by simply majorities are to be deputies; the number of deputies from each district depends on the number of members at the district conventions.

The Presidium of PRAA hopes that more former radio amateurs will resume their activities. The pity is that so many ex-hams do not apply for licenses. The spirit is willing but the flesh is weak? Some radio fans did not regain their licenses. They appealed to verification boards and in some instances received their longed-for papers. To encourage indifferent hams, the time for bringing licenses up to date has been extended for three months.

Considering the reduced number of radio amateurs, the Headquarters of PRAA made a decision to propose the liquidation of the functions of agents in some districts of Poland. The former agents are to hand over documents to other appropriate District Departments of PRAA. The District Departments of PRAA are authorized to commission the former agents to continue their functions or to designate others. From February 1, the radio amateurs of districts Bielsko Podlaskie, Chelm, and Zamosc belong to the district of Lublin; the radio amateurs of districts Ciechanow and Plock go to the district of Warsaw; Przemysl goes to Rzeszow; Slupsk to Koszalin; Walbrzych to Wroclaw; Wloclawek to Bydgoszcz; and Tarnobrzeg and Radom to Kielce. These organizational changes are to render the administration of PRAA more efficient.

Norms for staffing of PRAA are exceeded, the Presidium says. Salaried workers should be replaced by active hams.

At the request of the vice-president of PRAA Headquarters, SP3AUZ (the Polish Radio Videography Club) was founded on January 28, this year.



TAIWAN

Tim Chen BV2A/BV2B
PO Box 30-547
Taipei, Taiwan
Republic of China

After decades of endeavor, we are pleased to see that the Chinese government has decided to renew the licensing system with a ceiling of 12 ham stations to be distributed in 4 districts. The northern district will be allotted 4 stations, central 3, southern 3, and eastern, 2. We anticipate many license applicants, and the limit of 12 stations will not meet the demand. To solve this problem, club stations will mostly be the way to absorb more operators at the beginning.

The regulations governing ham-radio stations are under revision. The usable frequencies allowed will be only on the 40-, 20-, 15-, and 10-meter bands. The China Radio Association (CRA) is requesting the authority to add the 80-meter band for ham use in order to facilitate 5-band QSO possibilities. VHF and UHF are still out of the question. However, 144/430 were recently used by the Japan DXFF DXpedition on a temporary basis, so it is possible we can apply for them in like situations.

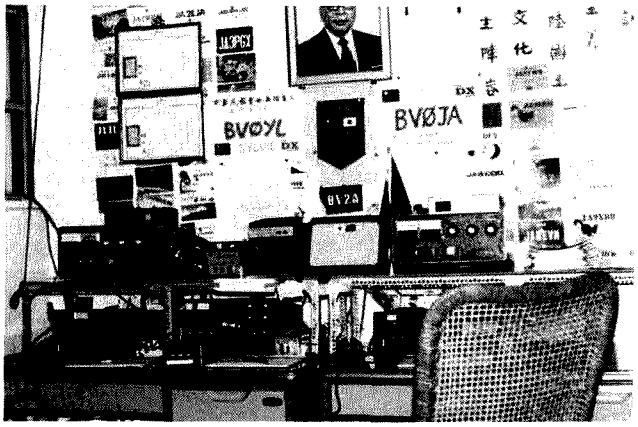
The Directorate General of Telecommunications (DGT) will give public examinations once or twice in a year. The first examination was scheduled for September. All participants have to pass the qualification test. It covers Morse code at 30 wpm on both sending and receiving for 3 minutes, radio principles, electricity principles, telecommunications law, international radio regulations relevant to amateur radio, English, and communications geography. Oral tests on alphabetical and numeral spellings are also required.

DXFF DXPEDITION

The Japan DXFF DXpedition group consisted of 12 members, including two XYLs and one reporter/photographer. They were divided into three teams and arrived on June 8, 13, and 14, respectively. As usual, the ham visitors wasted no time setting up station BVØJA/BVØYL and antennas immediately after their arrival in Taipei. The DXpedition venue was at the same place which had been used by former groups. It is facing a public park, with a spacious roof on a 12-story building for antenna installation good towards east, north, and west.

The special callsigns BVØJA and BVØYL were assigned for use by the OMs and YLs of the group. By estimate, over 15,000 QSOs were made during the 10-day operation. The most outstanding aspect of the DXFF group was the operation on 144/430 with AO-10 (B), from which nearly 200 QSOs (CW/phone) covering 4 continents (excepting South Africa and South America) were obtained. It is a record for ham operation with satellites in this area. We have informed the DXCC of these operations and callsigns which had been approved by the Chinese Government and considered legal for DX credits.

Shozo Hara JA1AN, president of JARL,



DXpedition station BVØJA/BVØYL.

recently made a courtesy call on C. C. Lee, Director of Post and Telecommunications, MOC. Their talk about world amateurs was fruitful and meaningful in promoting ham activities in our country. Therefore, further cooperation between JARL and CRA is expected. A second Japanese group was to visit BV-land in July, and the callsign BVØAB was requested for the mission.

After expedition activities, our visitors' stations had materially improved QSOs to world hams; we should be very appreciative of their efforts as they spent lots of time and money to carry out their missions. Perhaps there will be two bigger groups scheduling arrivals this fall; please look out for them.

Local authorities have so far approved four expedition groups from abroad; we are going to strengthen the ham movement gradually, although we do not have many stations at present.

There is no doubt that ham activities have become popularized step by step in this land. Enquiries by letters and phone calls are frequently received. Newspapers and the broadcast media are quite encouraging, giving us good comments. Furthermore, one of local TV stations, the CTS, had a vivid telecasting of our activity in its news program on prime time. Its lady reporter, Miss Lee, said, "Now I am also tempted by the hobby!" HI YL! Welcome to amateur radio!

"Why not have a telephony class?" asked Dr. Wayne Green W2NSD during his sojourn in Taipei with his XYL, Sherry, recently. (Congratulations, Dr. Green, for your new title.) You should be also pleased to learn that we are stepping forward, but we have to stick on CW/phone at the beginning. Thanks for your concern!

FCC 3, Hams Won

"I HAVE A SUSPICION that we're not going to lose this band, but that doesn't mean that ham radio is out of the woods," says **Art Rels K9XI.** Art, who is the editor of *220 Notes*, believes that hams have won this battle, although he cautions that further attacks on the 220-MHz spectrum allocation are likely. Incredibly, hams are buying 220 gear by the bushel. Part of the reason is the increasing popularity of digital modes of communication, like packet radio, which use the band for high-speed inter-group linking. The FCC received nearly 300 comments on the issue; most were rational discussions of the impact land-mobile radio would have on 220. This is in contrast to the deluge of unsupported whining the Commission had to wade through during the no-code disaster. According to Art, ". . . the future of 220 MHz is looking up!"

Packet Ears

SPEAKING OF PACKET RADIO, the ARRL is publishing a very informative newsletter for the packeteer, dubbed *Gateway*. It's available to everyone with an interest in the subject, although League members get a discount on the subscription rate. The second issue of *Gateway* described an HF packet bulletin board run by **Hank WØRLI.** Hank's BBS is one of the more popular systems on the east coast and can be accessed on 14.080 MHz using 200-Hz shift at 300 baud. If you would like more information about *Gateway* and packet radio, drop Editor **Jeff Ward K8KA** a note at 225 Main Street, Newington CT 06111. Tell him *73* sent you!

Ducky Wars!

NOW THAT NO-CODE is dead, it's time for a new divide-the-ranks issue: a national 144-MHz repeater standard. Right now we have two. Under the eastern plan, repeaters in the 146-148-MHz subband are spaced 15 kHz apart. The bandplan being used in the western part of the country has them 20 kHz apart. Obviously, this creates real nightmares for repeater coordinators in areas where both systems abut. Who's correct? Rumor has it that Mexico will be using the 20-kHz system (by governmental decree) very soon. Hams in states that border XE-land are going to have mucho problemos when they try to kerchunk their favorite machine—unless they switch their repeaters to 20-kHz spacing. But then what about the hams in states that border the states that border XE-land? You can easily see how the trouble quickly spreads across the nation. It gets really confusing when you realize that the ARRL promotes its own bandplan—repeaters west of the Mississippi are supposed to run inverted. Personally, I think we should implement a national 20-kHz-spacing system. Technically, it makes more sense than what we're doing now. What do you think?

73's Company

DID YOU EVER NOTICE that company is most likely to drop by when the place is a wreck? Well, it happened to us here at *73* a few days ago. It was a fine New Hampshire Friday, and everything we own was in boxes. The furniture was all shoved into one room, and the entire staff was decked out in our finest grubby attire, as we were moving to plush new offices about a mile down the road. Into the middle of this mess stepped **Grant W6NTK,** his family, friends, and two dogs! Grant had driven his RV from California to Maine and wanted to drop in and say hello. We had a very pleasant visit, with Grant demonstrating his allband mobile installation (including RTTY) which was very impressive. Not ten minutes after wishing Grant farewell, we heard a knock on the door . . . it was **Dean WT4A,** who had driven up from Florida! Needless to say, we didn't get a heck of a lot of moving done that afternoon.

Going, Going . . .

WILL HAMS LOSE still more spectrum to commercial interests? The FCC would like to reallocate half of our 160-meter band to non-government radiolocation. Docket 84-874 would move this service to make room for an expansion of the AM broadcast band implemented in the 1979 WARC. Though the amateur community was taken by surprise, the ARRL moved quickly, filing a motion against the NPRM just three days after it was announced.

Author! Author!

FAME AND FORTUNE are what *73* authors receive! We all have a story to tell. Why not tell it to the world? We are looking for articles that deal with the technical side of amateur radio. The how-to-build-it-and-why-does-it-work type of piece that you enjoy reading in *73* every month. It doesn't have to be complete plans for a 9600-baud frequency-agile kilowatt hand-held, just some little gadget that you or a friend have built. I won't tell you how much we pay for articles, but if we really like it, a well-written manuscript could pay for that new packet system you've had your eye on. And don't worry if you can't spell or if your paragraphs are one long sentence. We'll help you over the rough spots. Interested? Send an SASE to *73*, 80 Pine Street, Peterborough NH 03458, Attn: HTW. When your envelope comes back, it will have a copy of our author's guide in it.

Cheap Tricks

YAESU FT-757 OWNERS rejoice! From our something-for-nothing department comes word of a newsletter published by the **757 Club International.** It really looks like a great source of information about this popular rig, and the price is right. Membership in the club, which includes the newsletter, is free—just send a large SASE to 757 Club International, Box 5021-E, Spring Hill FL 33526.

Read This!

WHAT'S NEW WITH YOU? We would like to know just that. You may have noticed (especially if you're reading this) that *73* has a new column. "QRX" is about you—what you are doing, what you've heard, what you would like to do. Don't be shy: Send news items, comments, and what have you to *73* Magazine, 80 Pine Street, Peterborough NH 03458, Attn: QRX Editor. Try to double-space any typed items, and send along a picture if you can.

China Syndrome

WORKED CHINA YET? Neither have I, but there's hope for us little pistols. According to **Tim Chen BV2A/BV2B** in Taipei, exams for ham operators will be given by the Ministry of Telecommunications, and we may expect oodles of BY calls flooding the bands very soon. OK, maybe not flooding, but at least it will be a little easier to get that card you've been wanting. In the meantime, look for BY1PK around 14.155 MHz and between 14.180 and 14.190 MHz at 1400 and 1600 UTC. BY5RA has been heard near 14.195 MHz from 0800 to 1000 UTC.

Fight Back!

THE ARRL HAS FILED a Request for Issuance of Declaratory Ruling with the FCC that asks the Commission to exercise preemptive authority over state and local zoning regulations which affect transmitters and antennas used in the Amateur Radio Service. File formal comments (an original and four copies) with the Secretary, FCC, 1919 M Street NW, Washington DC 20554; refer to PRB-1. The deadline for comments is December 14, 1984.

A Times Square Data Display

Build this scrolling touchtone decoder for your favorite repeater. What you see is what you hear.

This is a project for repeater operators and people who want to see what they hear on repeaters, namely, touchtones™. It is a Times-Square-style scrolling touchtone data display. It is also a project that I wanted but kept putting off for all of the 12 years that I have been designing and building autopatches and touchtone repeater controllers. I could never justify dedicating a touchtone decoder to a function like this. Touchtone decoders were just too expensive, finicky, or bulky.

Well, things have changed! With its recent introduction of the TRK-956 DTMF (touchtone) decoder kit, Teltone Co. of Kirkland, Washington, will surely put a severe crimp in the 567 tone-decoder business. Priced at only $22.75, the TRK-956 comes complete with an M-956 single-chip DTMF decoder, a 3.58-MHz crystal, and a 22-pin IC socket.

The M-956 decoder is a CMOS chip that includes all filters, decoders, and timing circuits needed to implement a complete 16-digit DTMF decoder. Its block diagram is shown in Fig. 1. The decoder requires only a single +5-volt supply and has a measly current drain of only about 10 mA! By the way, Teltone includes with each kit sold their SC-1 application guide which explains all about telephone lines and signaling standards and has plenty of touchtone applications circuits.

Features

This circuit will display incoming touchtone digits beginning on the right side of the display and scrolling them to the left as new digits are received. The circuit shown in this article is capable of displaying 16 digits.

The circuit has several display-control buttons. A CLEAR button blanks the display and reinitializes memory. The SHIFT button will shift the entire display to the left one place and insert a blank character on the right end. A MATCH button is used for sequence programming (which will be explained later).

A useful feature that I included was that of code matching. A given sequence of numbers ranging in length from 1 to 16 digits may be programmed easily into the unit. Then anytime that exact sequence of numbers is received, the circuit will activate an alarm line. This feature is very handy for several purposes. For example, it can be used to dump an autopatch when an illegal phone number is dialed, or it can be used to set off alarm bells and sirens when a malfunction code is received on a telemetry downlink, or it can be used to unsquelch a station's speaker when an access code is received. I am sure you can think of many other uses.

The Circuit

When I started to design this circuit, I came to realize that a standard shift-register design would require at least 21 integrated circuits. That's a lot more wiring than I wanted to do. Since I am an advocate of the KISS design philosophy (Keep It Simple, Stupid!), I decided to utilize the marvelous power of the microprocessor to simplify. Using the Intel 8748 microprocessor, I

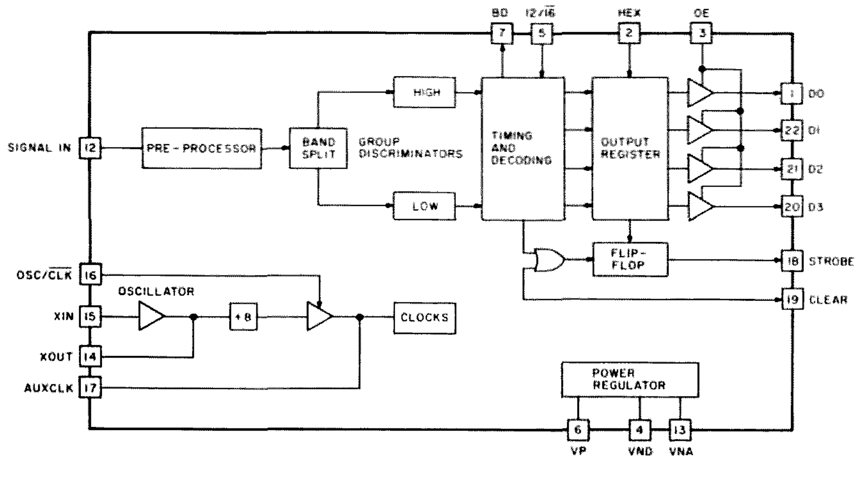

Fig. 1. Block diagram of the M-956.

was able to bring the circuit down to just four ICs, which is just about right for two evenings' construction time. The schematic is shown in Fig. 2.

The 8748 microprocessor, or course, controls it all. It receives the binary data from the decoder, transforms the data into 7-segment form, and then routes the proper display data to the segment drivers at the same time that it activates the appropriate digit driver. Every time a new digit is received, the microprocessor checks the currently displayed data to see if it matches a preprogrammed sequence that may have been stored in memory previously. If there is a match, the alarm line is set to a high state. The microprocessor also reads the switch inputs to check for any incoming commands. It does all this many times per second, so quickly in fact that it has no trouble keeping up with the fastest autodialers (about 16 digits per second).

I chose the 8748 for the job because it has all the ROM, RAM, and I/O capability needed on a single chip. I also had one in the junk box! Hi! I realize that not everyone has capabilities for programming EPROM-style microprocessors, so I will offer preprogrammed units at a reasonable price.

In addition to the microprocessor and the tone decoder IC, I used a CD4515 CMOS 4-to-16-line decoder to expand the output capability of the microprocessor. This IC has the capability of driving 16 output lines. These lines then go to discrete transistor digit drivers (Q1–Q12) which supply current to each display digit at the proper time. The microprocessor itself drives the 7-segment driver transistors (Q13–Q19).

Software

Since I am using the same

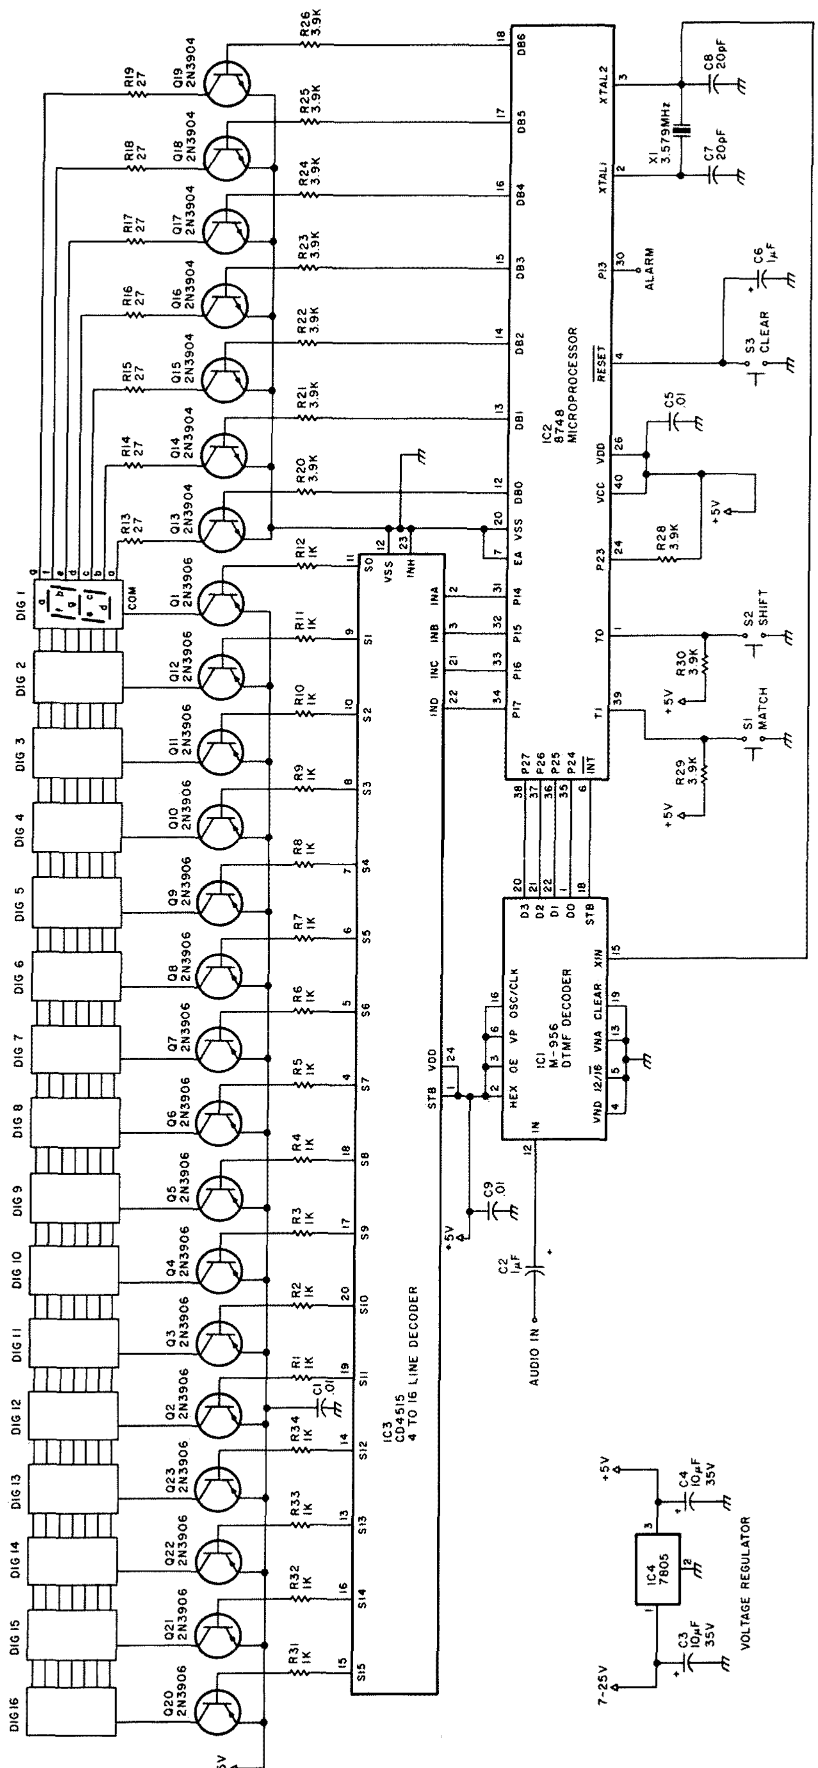

Fig. 2. Schematic diagram.

microprocessor for data display and telemetry transmission, I started the program (below) with a fast check to see if transmit or receive mode was selected. This is indicated by a high or a low on pin 24 of the microprocessor. If the input is low, the transmit routine is selected. Otherwise the program for data display will be executed. The program then initializes registers and memory space. Anytime the CLEAR button is pressed, the microprocessor will reset and re-execute this initialization sequence, thus clearing the display and memory.

Lines 180 through 270 comprise the main loop. Everything else is in subroutines. The main loop calls the display routine, DAGN, checks to see if all digits have been displayed, and then checks the INT input to see if there is a new digit incoming. In this way, new digits are read in only at the end of a display multiplex cycle. This is done to minimize display flicker and keep each digit at equal brightness. The command switches are then checked. If no commands are incoming, then the program just executes the main loop again.

The SHIFT subroutine, lines 280–520, shifts all data down one location in memory when either a new digit is received or the SHIFT button is pressed. A new digit is stored in the now vacant first memory location. If the SHIFT button was pressed, a blank is put in the first memory location.

The digit-display subroutine, DAGN (lines 580–790), pulls the digit to be displayed out of memory, looks up its 7-segment representation in the decode table (lines 1090–1250), and then outputs the digit address and the proper 7-segment code. Since the * and # figures cannot be displayed on a 7-segment display, I replaced them by the "o" and "-" characters, respectively. I also chose to display the sixteenth digit, "D" on most pads, as blank. Imbedded in the DAGN sub-

Program listing.

The touchtone data display.

routine is a small delay routine, lines 730-780, which is used to slow down the multiplex rate. Too fast a rate limits digit brightness, while too slow a rate would cause noticeable flicker.

The HOLD subroutine, lines 800-1000, moves whatever numbers are currently on the display into sequence memory when the MATCH button is pressed. It also sets a flag, F0, which tells the program to check the display digits against this memory for a sequence match anytime a new digit is received.

The last routine, CHECK (lines 1010-1180), does the actual comparison of display data and memory data. If a match is found, the alarm bit is set. Otherwise the alarm bit is cleared. Fig. 3 shows a memory-usage chart.

Construction and Operation

A printed circuit board was developed for this circuit and is shown in Fig. 4. Fig. 5 shows the parts placement. Note that the circuit board does not include the display LEDs themselves. Because of the wide variety

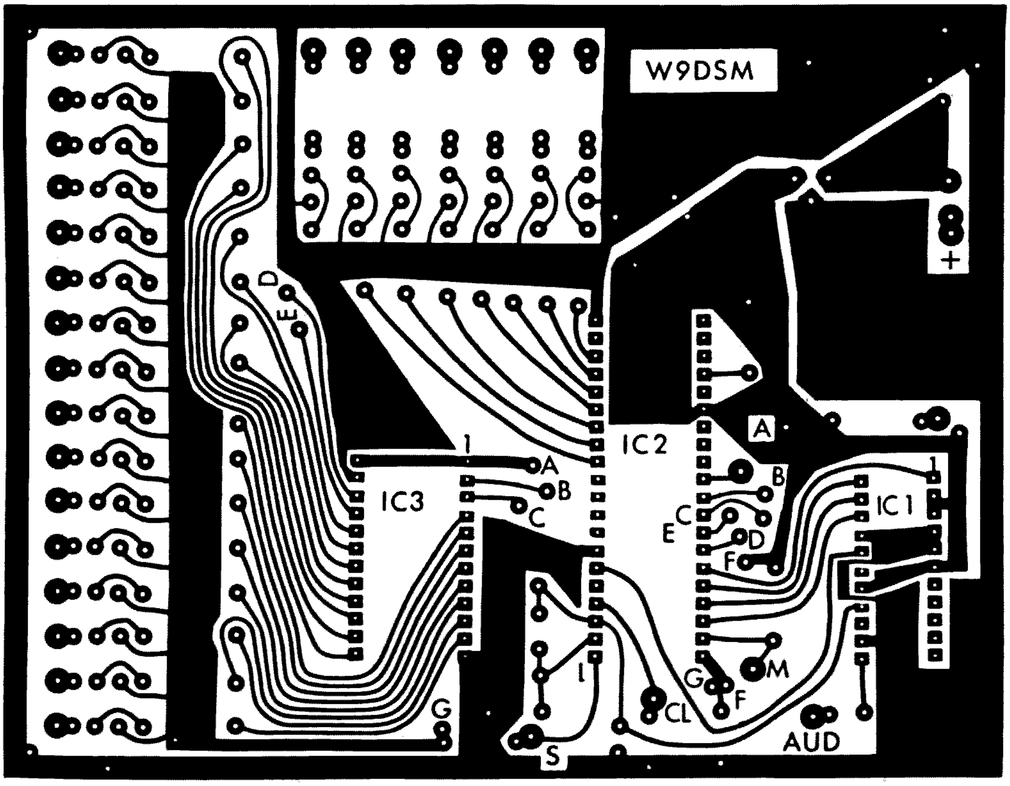

Fig. 4. PC board.

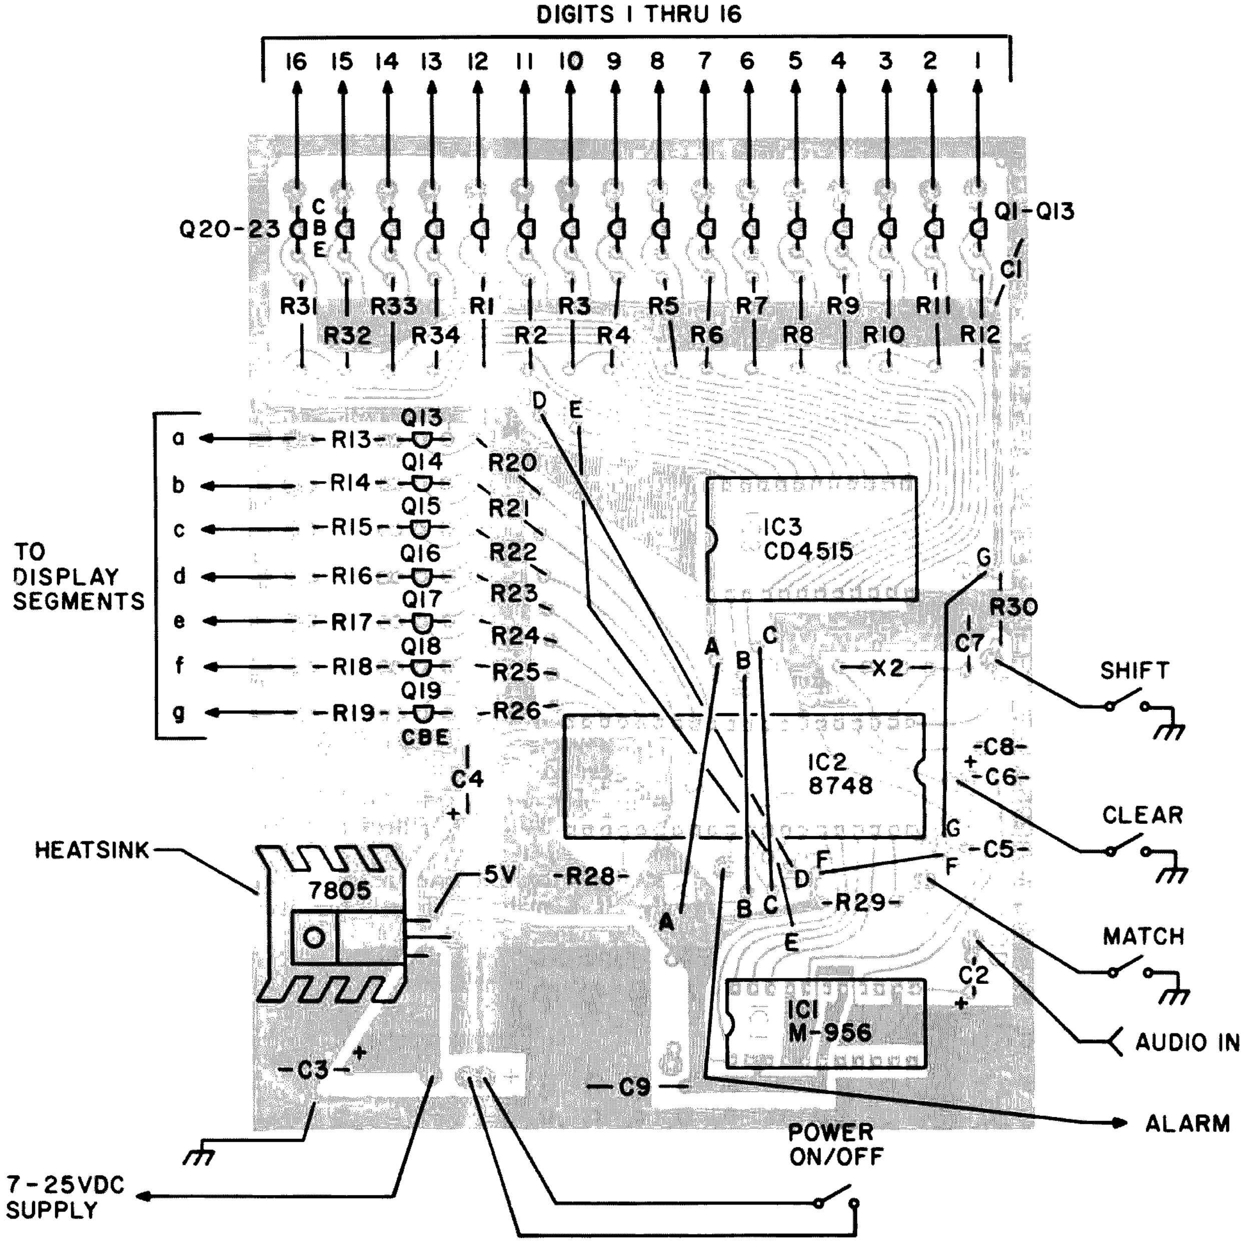

Fig. 5. Parts placement.

of LED displays that may be used in this circuit, I decided not to design a PC board for them. Any common-anode LED display may be used. If you decide to use the popular multi-digit stick-type displays, make sure that they are the multiplex type and not the direct-drive type. Whatever display you choose, wire all segment lines in parallel and bring out all anode lines separately. Your display may be any length you choose up to 16 digits. I limited my first prototype to only 12 digits. Simply leave out any digit drivers at the left side of the display that are unused.

The 5-volt regulator chip, IC4, can get quite warm during operation since the circuit draws about 250 mA. Because of this, a heat sink should be included. The PC board layout includes space for a TO-220-style heat sink.

There are seven jumpers, labeled A–G, which should be installed on the board *after* all other components are in place.

Initial power-up should be preceded by a voltage check with IC4 in place and IC1, IC2, and IC3 removed from their sockets. Check the power pins for proper voltages. These ICs are getting less expensive but still are not cheap enough to blow because of a wiring error or solder bridge!

Once the voltage check has been successfully completed, disconnect power and install all ICs in their sockets. Note that IC2 points the opposite direction of IC1 and IC3. Apply power. If all is well, the display should come up blank. Feed a source of touchtone audio to the decoder. The decoder requires an audio voltage in the range of about 150 mV to 2 V p-p. As each digit is received, it should be displayed at the right end of the display. Successive digits will cause previously received digits to be shifted one place to the left.

Pressing the SHIFT button also will cause digits to shift

Parts List

Quantity	Designation	Description	Cost
16	R1-R12, R31-R34	Resistor, 1k Ohm, ¼ W, 5%	$ .96
7	R13-R19	Resistor, 27 Ohms, ¼ W, 5%	.42
10	R20-R26, R28-R30	Resistor, 3.9k Ohms, ¼ W, 5%	.60
2	C7, C8	Capacitor, 22 pF, 50 V disc ceramic	.16
3	C1, C5, C9	Capacitor, .01 μF, 50 V disc ceramic	.24
2	C2, C6	Capacitor, 1 μF, 16 V electrolytic	.34
2	C3, C4	Capacitor 10 μF, 25 V electrolytic	.36
16	Q1-Q12, Q20-Q23	Transistor, PNP 2N3906 or equivalent	4.00
7	Q14-Q19	Transistor, NPN 2N3904 or equivalent	1.75
1	IC1	TRK-956 DTMF decoder kit	22.75
1	IC2	8748 microprocessor (see text)	50.00
1	IC3	CD4515 CMOS decoder	2.49
1	IC4	LM7805 5-volt regulator	1.59
16	DIG1-DIG16	LED, 7-segment common anode display	16.00
1	—	40-pin IC socket	.49
1	—	24-pin IC socket	.33
1	—	PC board	10.00
1	—	Heat sink, T-220 style	.25

NOTE: The crystal, X1, and 22-pin socket are included in the TRK-956 kit available from Teltone Corp., PO Box 657, 10801 120th Ave. NE, Kirkland WA 98033-0657; (206)-827-9626.

left, but instead of a new digit appearing, a blank will be inserted at the right end. This SHIFT button is very handy to insert blanks between incoming digits. It may also be used, when held down, to temporarily freeze what is on the display.

To program the unit to recognize a specific code, first press the CLEAR button to clear the display and memory. Then enter in the code that you want recognized. Do not enter any additional digits or blanks that you do not wish included in the sequence. Then press the MATCH button. From now on, any time that that exact code is received, the alarm line will be activated. Each time the code is recognized, the alarm line will stay activated only for as long as no additional digits are received. The matching process will be deactivated and memory purged when the CLEAR button is pressed.

Conclusion

I wish to thank Paul Hamilton WD4MQQ for his excellent photographic assistance and his PC board expertise. I also wish to thank Bill Kaylor W9DSM for developing the PC board layout and also for his nagging, which made me finally build this thing.

As I mentioned previously, I will make available preprogrammed and tested 8748 microprocessors for $50.00. Printed circuit boards are $10.00 each. ■

Color Computer SSTV: Part II

Complete the picture by adding weather-satellite facsimile to your new color SSTV system.

Editor's note: Part I of this article, detailing a complete color SSTV interface, appeared in the November, 1984, issue of *73*.

Clayton W. Abrams K6AEP

San Jose CA 95124

Dr. Ralph Taggart WB8DQT
602 Jefferson
Mason MI 48854

With the initial success of the K6AEP interface, SSTV software, and high-resolution display board, the next "new" application considered was facsimile. HF FAX operation has never had much of a following among amateurs but there is one area where amateur FAX techniques are booming—weather satellites.

Photo A. An infrared (IR) view of the NW quadrant of the earth as transmitted by the GOES E spacecraft using the WEFAX imaging format. A major frontal system can be seen wrapping around from the Gulf Coast up into New England. Broken frontal activity can also be seen in the Rockies and Plains states. Although some of the gridding of state borders and other features can be resolved, one of the higher-resolution formats (see photos) would be required to capture all the details in a picture of this type.

Thousands of amateurs and non-amateurs alike track the many different kinds of weather satellites now in orbit, and what has been needed for years is a nice, simple, and versatile display system that would

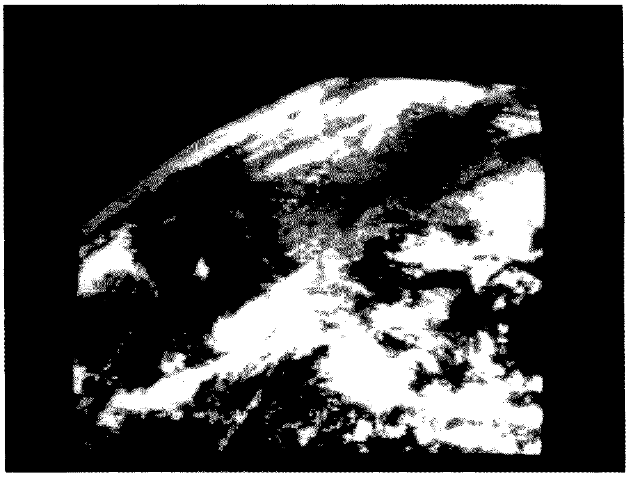

Photo B. Full-frame display of the NW quadrant of the earth as seen by GOES E in visible light. This image covers the same area as Photo A but visible-light imagery is rarely gridded. Even with the full-frame display the resolution achieved exceeds that of some small CRT display systems and is entirely adequate for most uses.

handle pictures from all of them! K6AEP was certain that the SSTV software could be modified for FAX display, and WB8DQT was equally certain that a multimode satellite interface could be designed to take advantage of the CoCo® as an image processor and display system.

With the two of us madly experimenting in our areas of expertise, we soon had a workable system up and running, and the results exceeded all of our expectations! With the satellite interface to be described this month (and with the high-resolution display board described in Part I) you can be scan-converting all types of US and Soviet weather-satellite pictures in no time at all! The mix of features available with the current software is mind-boggling compared to conventional techniques! Some of these features include:

- Full-frame display of imagery from all current operational satellites. These include both geostationary (US GOES, European METEOSAT, and Japanese GMS) and polar-orbiting spacecraft (US TIROS/NOAA and Soviet METEOR).

- The ability to capture extremely-high-resolution subsets of any images that exceed the theoretical resolving power of the image format.

- Computerized "zooms" on any portion of the image in memory.

- The ability to rotate images by 180 degrees, thus eliminating the upside-down pictures characteristic of south-to-north polar-orbiting passes.

- The capacity to enhance the contrast of the satellite picture—a real boon in the case of infrared polar-orbit imagery.

- Two different kinds of false-color display.

- The ability to generate hard copy using a graphics printer.

This is a mix of features you cannot find in any available display system, but there is even more! If you combine the SSTV interface (Part I) with the satellite interface to be described here, you obtain the following additional features:

- Complete HF FAX display capability for wirephotos and weather charts.

- The ability to record or transmit weather-satellite pictures in standard SSTV formats.

All of this may seem like quite a tall order but we can deliver—as we hope to demonstrate here. Let's get fired up and see how it's done!

Photo C. A NOAA 7 visible-light APT pass showing the east coast. Delaware, New Jersey, and Long Island show quite clearly in this full-frame display but much of New England is buried under a major cyclonic storm system in the process of moving out to sea. Lake Erie and Lake Ontario are visible at the top center of the display.

The Satellites

The one thing we do not have the space for is a description of the various satellite systems and image products. Your best source of information in that area is the *New Weather Satellite Handbook*, available at your local library (out of print). This publication provides all of the information on the satellites, their video formats, tracking and antenna alignment, construction of receivers, antennas, test equipment, and a full range of construction projects for FAX and CRT image display. If you are into satellites, you probably have the book already and can move directly to the CoCo scan-converter project. If you are new to the game, you had better find a copy so that you are ready to go when your hardware is on-line.

The Weather-Satellite Interface

At this point we will deal with how to condition and process the satellite signal for proper input to the CoCo. Satellite mode is relatively unimportant in the discussion which follows. Simply keep in mind that we are dealing with an amplitude-modulated 2400-Hz tone (black = minimum and white = maximum) with line rates of either 120 or 240 lpm (equivalent to either 2 or 4 Hz).

Each of the circuit descriptions to follow has several sections. The *Function* description tells what the circuit does; the *Operation* section describes how it works; the *Construction* section will describe any specifics that need be observed in laying out or wiring the circuit; the *Adjustment* section tells how to set up that part of the system. Actual operation of the complete interface will be described under "System Operation."

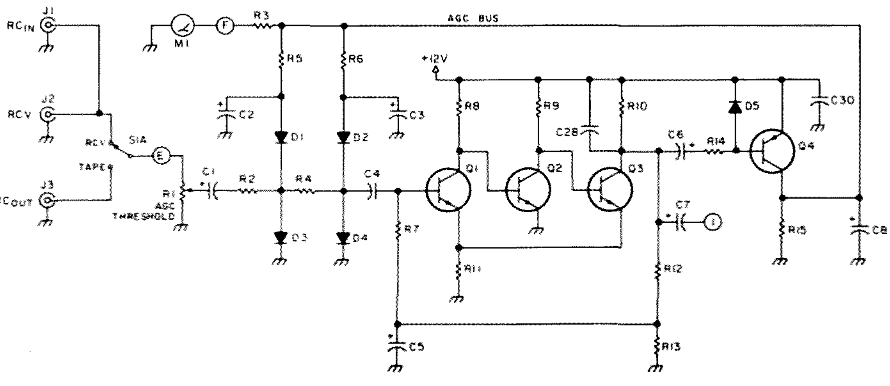

Fig. 1. Automatic gain control.

Main-Board Pinouts

Schematic Designation	I/O Function
A	Ground
B	+5 V (If regulator off board)
C	+12 V
D	−12 V
E	Video in from S1A
F	Agc meter
G	Contrast control
H	Contrast control
I	Video out to J7
J	Clock out to J4
K	Clock out to S1B
L	To Phase switch
M	To 120/240 lpm switch
N	Sync out to J6
O	To Reset switch

Front-Panel Controls and Indicators

- Power switch (If supply internal)
- Power lamp
- 120/240 lpm switch
- Phase switch
- Reset switch
- Agc meter
- Contrast control
- RCV/Tape switch

Rear-Apron Connections

Power	Ac or dc
RCV	From station receiver
RC Out	Right-channel tape output
RC In	Right-channel tape input
LC Out	Left-channel tape output
LC In	Left-channel tape input
Sync	To CoCo serial port
Video	CoCo right joystick port

Main-Board Controls and Indicators

Agc threshold	R1
Black level	R31
Clock freq.	C17
Vco lock	R42
Sync lock	D9 Indicator

Table 1. Packaging data.

One final note. It is assumed that the interface will be wired on a plug-in prototype card or on a PC board available from one of several vendors. The pinout designations in the following descriptions are arbitrary and the actual pinouts on your board will have to be related to these designations. Table 1 is provided to summarize the pinout designations used in the descriptions to follow. This information can be related to your board documentation or consulted as you work up your own layout. A list of vendors known to be supplying boards, kits, and wired-and-tested units is included in Part I of this article.

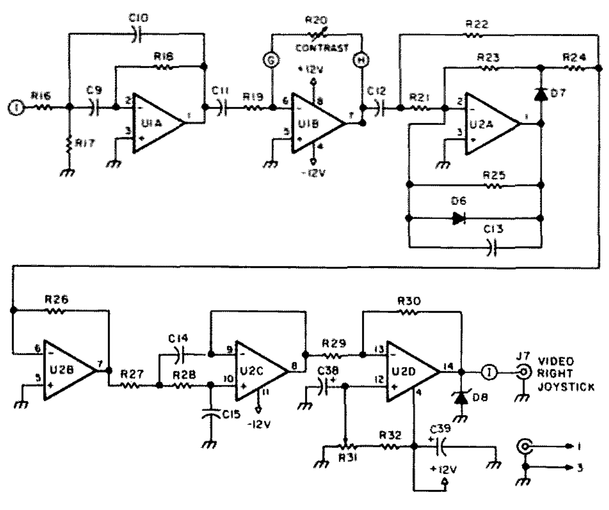

Fig. 2. Video circuits.

Automatic Gain Control (See Fig. 1)

Function. Since weather-satellite video involves amplitude modulation of an audio tone, the various video circuits are sensitive to peak subcarrier levels. With multiple satellite video sources, different receivers, tape systems, etc., constant readjustment of video-input levels would be required to maintain an acceptable gray-scale range. The automatic-gain-control (agc) circuits process signals of varying levels, delivering a signal of constant peak amplitude to the rest of the video processing circuits. Thus the video system functions with minimal adjustment over a wide range of input levels.

Operation. Video from the receiver is routed to J2 (Receiver) with J1 (RC In) in parallel to provide the capability to simultaneously display and record receiver signals. Video from the tape recorder is connected to J3 (RC Out). Selection of either receiver or recorder video is by means of the RCV/Tape switch (S1A). The video line from the switch enters the interface board at pin E with the Agc-Threshold control (R1) functioning as a load.

From R1, the signal is routed through a two-stage diode network (D1–D4) which provides attenuation as a linear function of the control voltage on the agc bus. From the attenuator, the signal is routed through a three-stage agc amplifier (Q1–Q3) with a fixed voltage gain of 100. Normally the output of this amplifier is about 2 V p-p. The amplifier drives the agc detector (Q4) which develops the agc control voltage on its collector. The attack time constant of the detector is a function of C6 and R14 while the decay time constant is determined by C8, R15, and the series resistance of R3 and the 50-microamp agc meter (M1).

If the peak input signal should increase, the agc bus voltage will rise, increasing the attenuation in the diode network and lowering the output of the agc amplifier to its previous value. Similarly, should input peak level decrease, the agc bus voltage will drop, decreasing input attenuation and raising the output of the agc amplifier. The output of the agc amplifier chain, maintained at a relatively constant peak level, drives the remaining video circuits at point (1). The agc meter serves to indicate the agc control voltage and is used to ensure that input signals produce control voltages in the most linear portion of the agc response curve (1–2 V).

Construction. Note that Q4 is a PNP transistor and must be installed with its emitter on the 12-V bus. Also note the polarity of C6 which is oriented differently from all of the other tantalum coupling capacitors.

Adjustment. For best results, the output from the receiver should be tapped at the top of the volume control through a .1-µF coupling capacitor to provide a constant output level that is independent of the receiver volume-con-

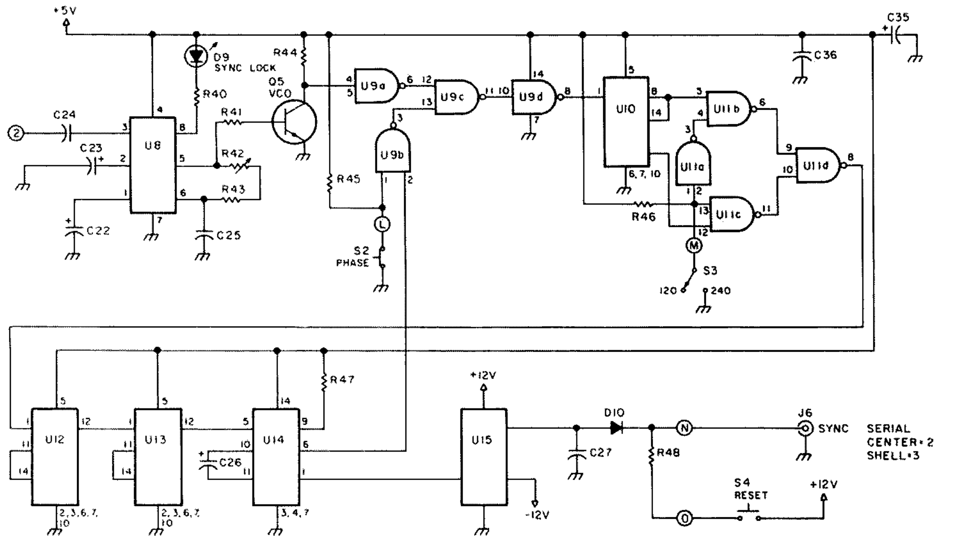

Fig. 3. Line synchronization.

trol setting. With noise output from a vacant satellite channel, adjust the Agc-Threshold control (R1) for an agc-meter (M1) reading of 15. The output of the tape recorder should be adjusted to produce an agc-meter reading between 10 and 20.

Video Circuits (See Fig. 2)

Function. The video circuits provide subcarrier filtering, detection, post-detection filtering, and gain adjustments to properly drive the joystick (A/D) input.

Operation. Video from the agc amplifier (point 1) is routed through an active bandpass filter (U1A) with a center frequency of 2400 Hz, a bandwidth of 1600 Hz, and unity gain. The filtered output drives a variable gain stage (U1B) with gain set by the front-panel Contrast control (R20).

U2A and U2B comprise a precision full-wave detector that generates a negative-going signal containing the modulation envelope superimposed on the post-detection 4800-Hz subcarrier component. U2C is an active low-pass filter with a nominal cutoff frequency slightly above 500 Hz. The roll-off characteristics of this filter ensure optimum resolution in the highest-resolution sampling modes.

U2D is an inverting amplifier that adjusts the video signal to the 0–5-V range required for the joystick A/D input. The offset is adjustable (R31) to set the desired black level while the Contrast control provides the drive adjustment that determines the maximum white level. D8 provides white-level clipping at 5.1 V. The detected waveform is routed off the main board at pin I and on to J7 (Video) on the rear apron. The center conductor of the mating jack for J7 is connected to pin 1 of the joystick plug while the shell (ground) is connected to pin 3 of the joystick plug.

Construction. The front-panel Contrast control should be wired so that minimum resistance corresponds to maximum CCW rotation of the control shaft. The joystick plug can be a hard item to obtain. The easiest approach is to disassemble a standard CoCo game joystick, since you get the plug with cable attached. The phono plug to J7 should be wired with the yellow lead to the center pin and the black wire to the shell.

Adjustment. Proper video adjustment requires the agc circuits to have been set up previously. Preset the Contrast control (R20) to the maximum CCW position and preset R31 so that the wiper arm is at ground potential. With the program running and video at the input, adjust R31 to just before the point where the black background starts to gray out. Then adjust the Contrast control for the most pleasing gray-scale response.

Line Synchronization (See Fig. 3)

Function. The business of transferring incoming video into memory must be very closely related to the satellite line rate. The actual loading operation is initiated by line-sync pulses which must occur at the same rate at which the satellite video is being transmitted and at the same time a line of satellite video begins. The line-synchronization circuits provide an accurate 2-Hz (120-lpm) or 4-Hz (240-lpm) trigger pulse to control the loading operation and also provide for proper phasing—the ability to shift the position of the line-loading pulse to ensure that it coincides with the beginning of satellite video lines. In addition, provisions are included to ensure the required timing accuracy for both live and tape-recorded imagery.

Operation. The heart of the sync circuit is a phase-locked-loop (PLL) tone-decoder chip (UB) which is designed to lock to a 2400-Hz reference signal at point (2). Sources for this reference tone are discussed under the heading of "Clock Circuits," below. With 2400 Hz applied at point (2), the internal voltage-controlled oscillator (vco) of UB will lock to this signal since the vco adjustment control (R42) of U8 has been set to free-run near 2400 Hz. When U8 has locked to the tone at point (2), an internal-control transistor pulls low and lights an indicator LED (D9—Sync Lock) to show that lock has occurred. The 2400-Hz vco signal is buffered to TTL levels by Q5 and applied to a set of gates in U9. U9 controls the phasing function which will be discussed below.

For the moment, let us assume that the 2400-Hz vco-derived signal is gated through U9 and on to U10—a divide-by-12 counter. Two outputs are available from U10—a divide-by-6 output (400 Hz) at pin 8 and a divide-by-12 output (200 Hz) at pin 12. U11 is wired as an SPDT digital switch which selects the 400-Hz output in the 240 position of the lpm switch (S3) or 200 Hz in the 120 position. The output of U11 is routed through two decade counters (U12 and U13), providing a total frequency division of 100. With the lpm switch in the 240 position, the output of U13 is a 4-Hz square wave, while in the 120 position it is a 2-Hz square wave. The output of U13 triggers a single-shot

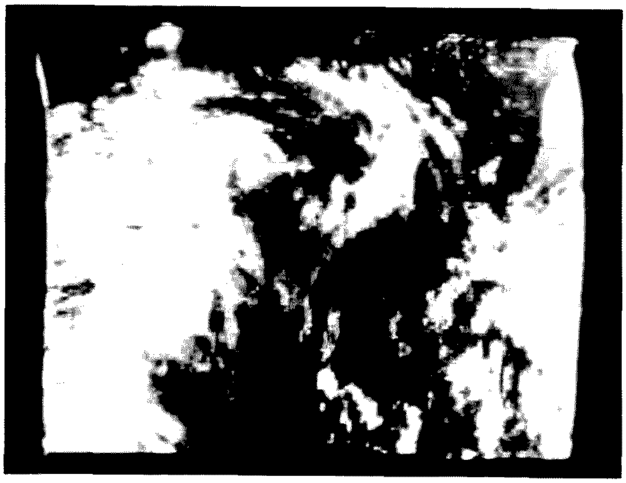

Photo D. A full-frame display of a "standard" 120-lpm Soviet METEOR display. The 120-lpm METEOR imagery does a great job on clouds but land/water features are difficult to discern unless lighting angles are almost perfect. 240-lpm "advanced" METEOR transmissions do a superb job on land/water features but these spacecraft are apparently still experimental and hence their service life seems short; they are on only intermittently.

(U14) which provides a 5-ms line-trigger pulse at either a 4-Hz or a 2-Hz repetition rate. This pulse is buffered by U15 to RS-232 levels to drive the CoCo serial port via the Sync connector (J6) on the rear apron. The Reset switch—a normally-open push-button—is wired to provide +12 V to the RS-232 line for manual reset.

Although the PLL and digital dividers provide the proper line-trigger rate, they are not sufficient to ensure that triggering is in phase—a condition where the line-trigger pulse corresponds to the start of a line of satellite video. Since it is desirable that the interface be usable in a wide variety of FAX formats, a simple manual-phasing circuit is provided. U9A buffers the vco-derived 2400-Hz tone, which then is applied to one input (pin 12) of U9C. The other input (pin 13) is derived from the output of U9B. This input is normally high since one input of U9B (pin 1) is normally held low by the normally-closed Phase push-button switch (S2).

Thus the 2400-Hz reference signal is typically gated through U9C, through U9D (a simple buffer), and on to the divider chain. When the Phase switch is pressed, however, it will open, causing the pin-1 input of U9B to go high. The output of U9B is then controlled by the status of the other input—pin 2. This pin is connected to the Q output of the 5-ms single-shot. Normally this pin is low, but for 5 ms of each line, the SS-trigger interval, pin 2 of U9B is pushed high, causing the output of U9B to go low for the 5-ms trigger interval.

This prohibits the 2400-Hz reference signal from going through U9C for the 5-ms interval, causing a 5-ms counting error once each line pulse for as long as the Phase switch is depressed. This causes the trigger repetition rate to be slowed (by about 2%), and since the trigger rate and the satellite line rate are no longer in step, the edge of the satellite image will migrate toward the left edge of the TV screen when the Phase switch is held open. When the left picture edge is aligned with the left edge of the TV screen, indicating a properly phased display, the Phase switch is released, the output of U9B goes high, and the 2400-Hz signal is gated through U9 without interruption, thus restoring the proper trigger rate.

Construction. The only note here is not to confuse the Reset and Phase push-button switches. The Reset switch is a normally-open type while the Phase switch is normally closed.

Adjustment. With 2400 Hz applied at point (2), adjust the vco adjustment control on the board (R42) until the Sync-Lock indicator on the board (D9) comes on. R42 should be set to the midpoint of the range where D9 provides a solid lock indication. A logic probe on pin 6 of U14 will show a series of short, high pulses indicating the proper operation of the divider chain. The pulses should be noticeably faster in the 240 position of the lpm switch than they are in the 120 position.

Clock Circuits (See Fig. 4)

Function. The clock circuits are designed to provide a 2400-Hz reference signal for both real-time and recorded-image display. The subcarrier signals of the US GOES and TIROS/NOAA spacecraft are phase-locked to the video line rate and could be used as a frequency reference. Unfortunately, this is impractical for several reasons. In the case of the GOES spacecraft, occasional modulation anomalies will drop the subcarrier black level to 0%, causing the line-sync circuits to lose lock and hence synchronization.

In the case of the TIROS/NOAA spacecraft, signal fades resulting in high noise levels also can cause sync lock to be lost. In addition, the standard Soviet METEOR spacecraft have subcarriers that are not locked to the video line rate and hence cannot serve as a suitable frequency reference. HF FAX signals have a variable subcarrier frequency (subcarrier FM modulation identical to the video swing for SSTV) so that sync lock is not possible with these services.

In order to make the interface compatible with the greatest range of FAX services, a crystal-controlled 2400-Hz signal source is employed. The crystal sync source is used directly during live image

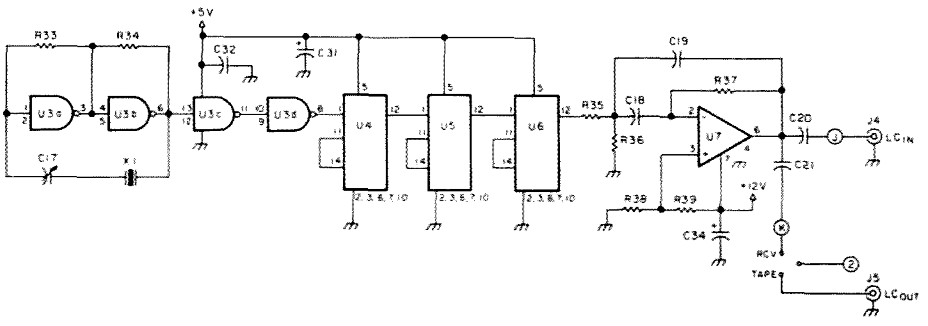

Fig. 4. Clock circuits.

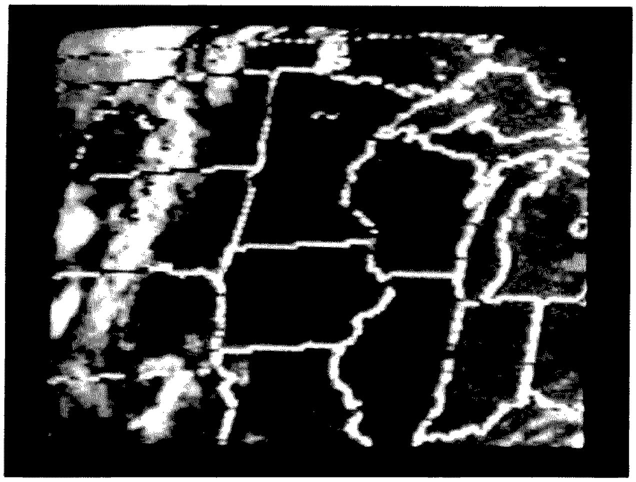

Photo E. Example of High Resolution 1 sampling of an IR WEFAX frame such as in Photo A. It shows a frontal system extending down the central Dakotas into Nebraska.

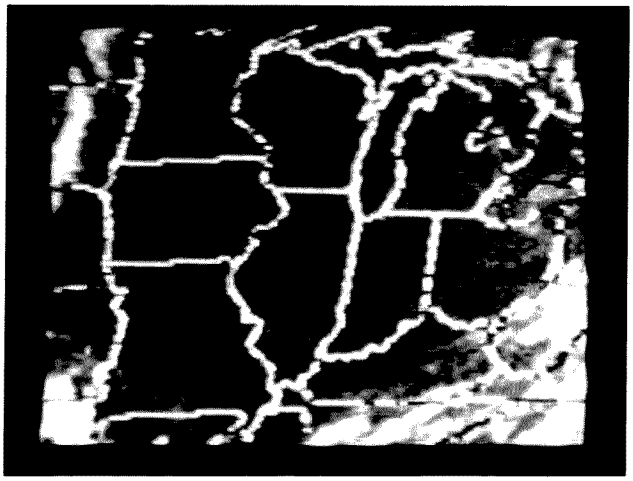

Photo F. The area in Photo E six hours later. In the upper-left corner of the image you can see that the front has intensified and that the system has moved into eastern South Dakota with some low-altitude clouds (indicated by their darker-gray color) moving into western Iowa.

display and is also recorded on the left channel of a stereo tape system while the video subcarrier signal is simultaneously recorded on the right channel. During playback, the line-sync PLL is locked to the recorded tone on the left channel and will effectively track frequency variations caused by tape speed changes during recording and playback, thus maintaining line synchronization.

Operation. U3 functions as a crystal-controlled oscillator/buffer operating at 2.4 MHz with fine frequency adjustment provided by C17. The 2.4-MHz signal is divided by 1000 using three decade counters (U4, U5, and U6). The 2400-Hz square-wave output from U6 is passed through a 2400-Hz active filter stage (U7) to convert the square wave to a sine wave. When the RCV/Tape switch (S1B) is in the RCV position, the PLL tone detector in the line-sync circuit is driven directly by the 2400-Hz crystal reference. A sample of the 2400-Hz signal also is routed to the left channel input of the recorder (LC In) at J4. With the switch in the Tape position, the PLL is driven by the signal recorded on the left channel (LC Out) via J5.

Adjustment. The only operational adjustment is to set the oscillator output accurately to 2.4 MHz by adjusting C17. This can be accomplished in one of three ways:

(1) Connect a frequency counter to pin 8 of U3 and adjust C17 for a frequency of 2.4 MHz to the resolution limits of the counter.

(2) Calibrate a receiver using WWV and a crystal calibrator. Connect a short test lead to pin 8 of U3, loosely coupling the lead to the receiver input. Adjust C17 to obtain precise zero beat at 2.4, 4.8, or 7.2 MHz. The latter frequency is useful for ham-bands-only transceivers.

(3) Display live images using the interface and WEFAX software. If the picture margin drifts to the right as the image reads out, the oscillator frequency is high. If it drifts to the left, the frequency is low. Adjust C17 until the margins are precisely vertical.

Packaging and Power Supplies

There is an old saying in the home construction game that once you have the boards wired you may be almost half done! What kind of packaging you use is pretty much up to you. In the case of the WB8DQT prototype, the display board was placed in its own metal enclosure with a 5-V regulator chip to run the board off the station's +12-V bus. Display-board power drain was measured at 600 mA.

The interface board was dropped into its own cabinet along with a small receiver. The +5-V interface requirements were taken care of with a 5-V regulator chip on-card and the current drain on the +12-V bus was 280 mA. The −12-V drain was minimal—slightly less than 20 mA. Required front-panel controls and indicators include the 120/240 lpm switch, the RCV/Tape switch, the Phase and Reset push-button switches, the Contrast control, and the agc meter. If the power supply is internal, you will also need a power switch and a power-indicator lamp.

The rear apron tends to be a busy-looking place with lots of cables heading off to other gear. There are a total of five audio leads —RCV (receiver output), RC In and LC In (right- and left-channel tape-deck inputs), and the RC and LC Out jacks (tape-deck right- and left-channel outputs) —where you should use standard shielded audio cables (phono-plug terminations) for the interconnections. The Video cable runs from the rear apron to the right joystick port of the CoCo while the Sync cable runs from the interface rear apron to the CoCo serial port. Although not absolutely necessary, it is helpful if the output from the receiver has a constant level—if only to simplify maintaining constant recording levels. A shielded audio lead coupled to the top of the receiver volume control through a .1-uF capacitor should do the job nicely with most receivers.

Tape Equipment

Obviously, the minimal satellite installation consists of the interface, display board, 64K CoCo, and your satellite-receiving gear. In order to make the most of the program features, however, you really should include a good (by music standards) cassette or reel-to-reel stereo tape deck. Regular cleaning and pressure-pad maintenance will keep almost any recorder up to par if you use high-quality tape. Taped transmissions never have

Photo G. A High Resolution 1 image obtained from a NOAA 7 visible-light APT pass showing the Great Lakes in considerable detail. A multitude of small lakes are clearly visible in southern Canada. For the ultimate in high resolution you can use the HR-2 format as shown in Photo H.

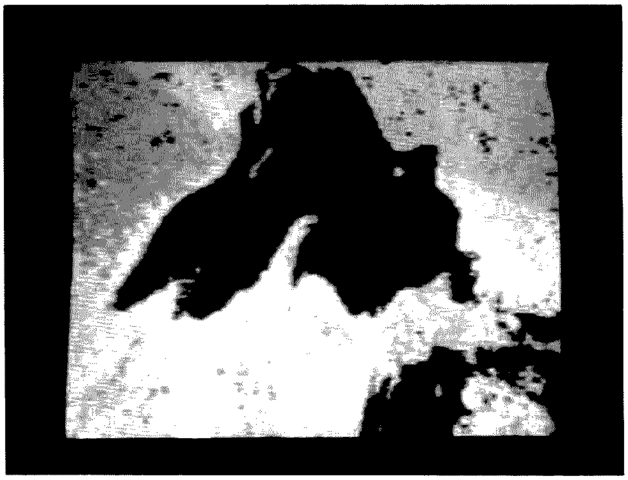

Photo H. The HR-2 format for Photo G. Lake Superior takes up much of the image area. The resolution of the HR-2 format equals the theoretical resolution limit for APT and WEFAX imagery and reveals details that are beyond the capacity of most systems.

quite the quality of "live" displays, but you will rarely notice the difference in practice. All of the photos used to illustrate this article are taken from tape, and the versatility of the program routines possible with tape makes it well worth the marginal loss in image quality.

In order to keep things simple, recordings should be made at constant input and output levels. The output level is easy—simply set it for maximum on both the left and right channels for most decks. Assuming the system has been set up as specified (video into the right channel, sync into the left), you should set the left-channel recording level for 0 VU with the interface running. With the receiver set to an empty channel (no satellite signal), set the right-channel recording level for a mid-range reading (−10 to −7 VU on most decks) using the noise output of the receiver as the signal source.

System Operation

What follows will be a very brief outline of the operation of the major routines in the present WEFAX Rev.3 program available from K6AEP. The software will certainly evolve with time, but most of the evolution will be "bells and whistles" in the sense of new routines. The basic image-display routines should remain fairly stable and you should have little trouble relating the instructions which follow to the extensive program documentation you will receive with your software.

As we discuss program features, we will have occasion to talk about two different displays—what we will call the "CoCo display" and the "image display." The CoCo display is simply the normal computer monitor where prompts, menus, and inputs are displayed. The image display is the monitor where the output of the display board is viewed.

Loading the Program. Insert the cassette and rewind if required. Preset the cassette volume level to about 5, set the cassette recorder to play, type CLOADM, and hit the <ENTER> key. The cassette machine will start to run and an S will flash in the upper-left corner of the CoCo display. The display board and interface should be powered up at this time, but pay no attention to the image display—expect garbage! When the WEFAX program is found, the flashing S will change to a flashing F and a short notice will print out to the effect that the WEFAX program is loading and will execute automatically when loaded. This magic event is easy to spot—you will suddenly get the main menu display (shown in Fig. 6) and the image display will show a random but static pattern based on the contents of the display RAM at power-up.

Virtually everything in the program starts with the main menu, and no matter where you are in the program you almost always can get back to this menu by hitting the <CLEAR> key on the CoCo keyboard. If you find the random-image display a bit disconcerting, you can get a grayscale display (actually color bars) by typing I followed by G followed by <CLEAR>. If your monitor is like most, you will have considerable vertical overscan on the image display. We would suggest adjusting the monitor height control to compress the display slightly to minimize the loss of picture information at the top and bottom of the screen.

Notes on Contrast Settings. At this point we will assume that the interface has been checked out as noted in the *Adjustment* section of each circuit description. If not, this is the point at which to complete checkout. The only variable that remains to be considered is the proper Contrast setting for each class of satellite. The first time or two you display a given type of picture you can expect to jiggle the Contrast setting until you get the best image display for that mode. Once you have determined the optimum setting for each mode, you should mark it on the front panel. You probably will end up with distinctly different settings for WEFAX, APT Visible, APT IR, 120-lpm METEOR, and 240-lpm METEOR. Alternatively, you may wish to install a small rotary switch on the front panel to switch in a small PC pot for each mode. With the switch positions properly labeled, you need only optimize each pot in turn, after which you can use a switch setting appropriate to the mode you wish to display.

Primary Image Display

General Notes. The Interface RCV/Tape switch should be set to RCV for "live" display directly from the receiver or to Tape for recorded display. Early experiments are best done with tape as you can always rewind the tape if you make a mistake, or you can display a full frame followed by one of the high-resolution formats, etc.

All image displays will begin with the R option from the main menu. This will reset the image display and the incoming picture will begin to read out. At the same time, a secondary menu (Fig. 7) will appear on the CoCo display and will provide you with your display options following phasing. The image display can be "frozen" at any time by hitting the <CLEAR> key, and the CoCo display will return to the main menu.

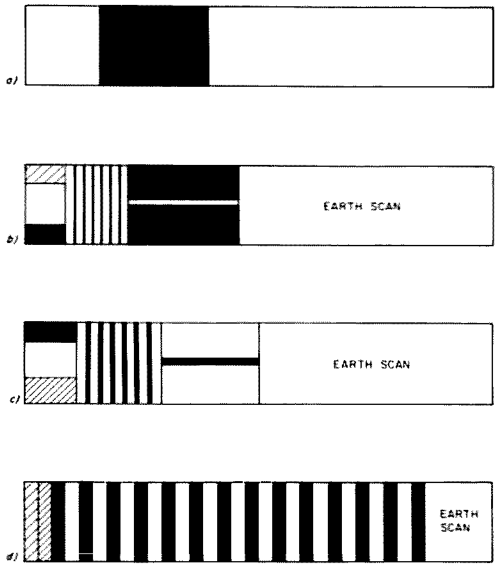

Fig. 5. Diagrams of line-sync pulses for the various satellite-video formats. Proper phasing of satellite pictures requires recognition of each kind of pulse. The Phase switch is pressed until the desired sync pulse moves across the screen and just off the left edge of the display. (a) shows the WEFAX line pulse—a simple black bar on a white background. It is transmitted during the phasing interval at the start of a GOES or METEOSAT frame transmission. (b) shows the sync pulse for NOAA visible-light APT imagery. It consists of seven cycles of 1040-Hz subcarrier modulation, followed by a black interval representing the scanner's view of space just prior to the start of the earth scan. Once each minute a white minute marker bar will interrupt the black space scan. The essential cues for the visible-light sync pulse are the black space scan and usually high-contrast video in the earth scan. Just to the left of the pulse train is a telemetry signal that is displayed as horizontal gray-scale data. (c) shows a typical infared (IR) line pulse in the NOAA APT format. This pulse is also seven cycles in length but it is seven cycles of 832-Hz modulation so it is somewhat wider than the visible-light pulse. The IR pulse is followed by a white interval (cold) representing the space scan. The earth scan is typically quite white and low in contrast. IR minute markers are black. To the left of the pulse is a telemetry gray-scale pattern similar to that of the visible-light pulse. (d) is the line-sync pulse for standard 120-lpm METEOR imagery—a long 13-cycle pulse that is very easy to recognize. The earth scan data is immediately to the right of the pulse while vertical gray-scale stripes are immediately to the left of the pulse. All of these pulses are enlarged illustrations—much as you might see with the HR-1 or HR-2 display formats. They are quite easy to recognize in full-frame display however, once you are familiar with their appearance.

WEFAX Display. Set the 120/240 lpm switch to 240. When you hear the characteristic 300-Hz "start" tone, simply hit R from the main menu and watch the display. You should see a white background with a vertical black bar somewhere in the image display area (shown in detail in Fig. 5(a). Press and hold the Phase switch and this bar should march step-wise toward the left edge of the image display area. Allow the bar to move off the display to the left and release the Phase switch. About 20 seconds after the end of the start tone you should hear some rough subcarrier modulation as the picture header begins to print out.

At this point, press key 1 and the WEFAX picture will begin to display from the top of the image display area. When the display reaches the bottom of the screen, press the <CLEAR> key to freeze the image and return you to the main memory. Note that with the US GOES spacecraft the picture starts about 20 seconds after the start tone. The European METEOSAT delays only five seconds, so you will have to hustle to complete the phasing operation.

Photo A shows a typical infrared (IR) WEFAX display, while Photo B is a visible-light example.

APT Display. Images from the TIROS/NOAA satellites are transmitted continuously in the APT format and display can begin whenever the signal rises out of the noise and can continue until the spacecraft begins to approach the opposite horizon. Preset the 120/240 lpm switch to 120 and hit R from the main menu to start display.

Phasing with APT is governed by which image, visible light or infrared, you wish to display. Daylight passes will have both formats available while night passes will have a black visible-light display and only IR data will be useful.

I — TEST INTERFACE
R — RECEIVE HIGH DENSITY FAX
L — RECEIVE LOW DENSITY FAX ON TRS80C
D — DISPLAY IMAGE IN MEMORY
Y — MEMORY CHANGE
C — DISPLAY COLOR IMAGE IN MEMORY
T — PRINT PICTURE ON SCREEN
S — SELECT PRINTER SPEED

KEY 3 = HIGH RES 1
KEY 4 = HIGH RES 2
KEY 5 = HF FAX FAST
KEY 6 = HF FAX SLOW
KEY R = ROTATE PICTURE
ANY OTHER KEY WILL END

Fig. 7. Secondary display menu, WEFAX program.

Photo I. Polar-orbit infrared (IR) imagery in low contrast.

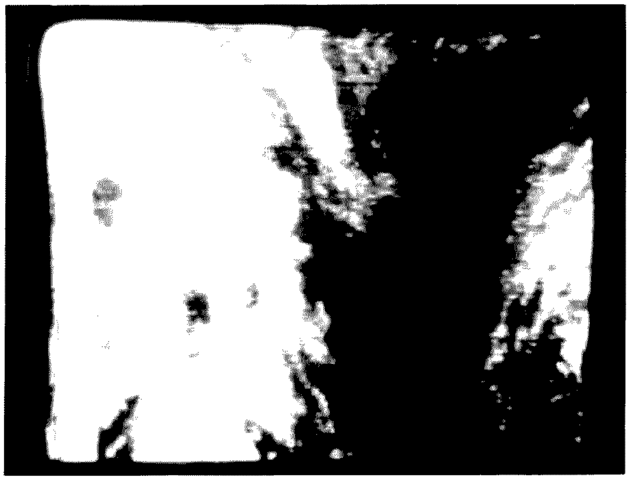

Photo J. Once the display has been optimized using the Contrast control, the image in memory can be enhanced using the contrast enhancement routine. Unlike other routines, enhancement alters the image in memory.

The visible-light sync-pulse train is shown in Fig. 5(b) while the IR-sync-pulse sequence is shown in Fig. 5(c). To display visible-light imagery, simply press and hold the Phase switch until the visible-light sync pulse passes off the left edge of the display. If you want IR display, simply hold the Phase switch until the IR pulse has moved off the left edge of the image display area. With either visible or IR phasing complete, hit key 1 to restart the display from the top of the image display area.

With a simple omnidirectional antenna you can expect to receive at least 10 to 12 minutes of imagery on a good pass. If you keep the display going unattended, the image will automatically reset as it reaches the bottom of the screen. For the first look at a pass, you may wish simply to let it scroll in this fashion. Once you have an idea of the features of interest, you can run the tape again and when you get to the point where you want to display the material, simply hit either the interface Reset switch or key 1 on the keyboard. Once the display fills up, simply hit <CLEAR> and the image display will be frozen while the CoCo display returns to the main menu. Photo C shows a sample of visible-light imagery from a daylight APT pass.

METEOR Display. Soviet polar-orbiting METEOR spacecraft come in two varieties—the standard 120-lpm spacecraft and the rarer 240-lpm birds which are apparently still experimental. Both types of METEOR imagery are restricted to visible-light data from daylight passes. For 120-lpm METEOR display you should preset the 120/240 lpm switch to 120 and hit R from the main menu to start display. The 120-lpm "standard" METEOR sync pulse is shown in detail in Fig. 5(d). As the image reads out, press and hold the Phase switch until the sync-pulse train marches out of view to the left of the image display. Release the Phase switch and hit key 2.

Like the APT format, METEOR pictures are continuous and you can scroll through an entire pass or hit the Reset switch to reset the display whenever desired and the <CLEAR> key to freeze the image display and return to the main menu. Photo D illustrates the results from a typical "standard" METEOR pass.

240-lpm "advanced" METEOR operation is similar except that the 120/240 lpm switch should be in the 240 position and you should hit key 1 following phasing.

High-Resolution Display

In order to provide for the display of extremely-high-resolution data, two high-resolution formats, High Resolution 1 and High Resolution 2, are supported by the WEFAX program. In each we sample a progressively smaller subset of the image with the capability of resolving finer detail. Prior to using one of these formats, you should display the entire image of interest to determine what features you wish to emphasize. Once this has been done, note some easily-recognized feature a short distance above the feature you are interested in. This feature will be the "recognition" feature and will tell you when you should shift to the high-resolution mode.

High Resolution 1. This is an intermediate format that will exceed the resolution limits of most CRT systems and many FAX displays. Assuming you have located the picture-area of interest to you and a suitable recognition feature, begin display with the main-menu R option and proceed to phase the image. In this case, however, you should phase the image so that the feature of interest will read out on the left half of the image display area. Key either 1 or 2 (depending upon mode) and watch for the recognition feature. As it begins to read out, simply hit key 3 and the High Resolution 1 sampling will begin. When display is complete, hit <CLEAR> to freeze the display and return to the main menu. Examples of HR-1 images are provided in Photos E and G.

High Resolution 2. The resolving power of this format exceeds that of any of the satellite formats and you can expect to see details that almost no one else can resolve. Start with R and phase the display so that the feature of interest will read out just to the right of the left image display margin. Key either 1 or 2 and watch for the recognition feature. As it starts to read out, hit key 4 and your HR-2 image will load quickly. Press <CLEAR> to freeze the display and return to the main menu.

An example of the HR-2 format is provided in Photo

Photo K. A full-frame display from a NOAA polar-orbit pass. The Great Lakes region is buried under a huge compound frontal system shaped like an upside-down V. Now see Photos L and M.

Photo L. An HR-1 display of the center of Photo K. The southern part of Lake Huron and all of Lake Erie can be seen between the open angle of the "V".

Photo M. An HR-2 view that reveals even greater detail, including a cloud "stringer" stretching across Lake Huron, a feature that is invisible in Photo K and barely resolvable in Photo L.

H. This is a demanding format due to the small area sampled but if you don't quite capture the area you want, simply run the tape back and try again. As you can see, the results are well worth the effort!

Display Options

Although most people would be quite happy just to be able to capture the full-frame or high-resolution formats, there is still quite a bit that can be done once the image is in memory! To access these functions, simply type D from the main memory and you will get a menu like that shown in Fig. 8(a). The functions you will use most often on this menu are summarized below. You can try these options in any order and as often as you like. Although the display will change with each option, the original picture will remain unaltered in the main memory.

(a)

DISPLAY PIX IN RAM
L = LOW DEN PIX
R = ROTATE PICTURE
T = TOP HALF
B = BOTTOM HALF
P = TOTAL PIX
1 TO 8 QTR FRAME

(b)

1	2
3	4
5	6
7	8

(c)

T
B

Fig. 8. (a) Display options menu. (b) and (c) Zoom formats.

Picture Rotation. South-to-north passes of polar orbiters will read out a picture in which south is at the top (start) and north at the bottom (finish); basically, the picture is upside down! If you type R from the display memory the image display will be rotated 180 degrees, and such inverted images will now be upright with north at the top. This neat software trick sure beats turning the monitor upside down or standing on your head to view the image!

Top and Bottom Image Subsets. Although the image in memory is stored in a 256 × 256 format, the standard display board format is 256 × 128, which means you lose some vertical resolution relative to the picture actually in memory. You can get all the resolution in memory by hitting either T or B, displaying the top or bottom half of the image in memory, using the entire image display area. Although this will distort the aspect ratio slightly—the pictures will appear "stretched" vertically—it is a quick way to look for fine detail that may be lacking in the full-frame format. The T and B formats are shown in Figs. 8(b) and 8(c).

Image Enhancement. IR imagery—particularly APT—can appear quite white and washed out, especially during the winter months, due to a lack of strong temperature differences between land and sea surface and overlying clouds. Careful adjustment of the Contrast control will help, but the pictures still will be pale compared to their visible-light counterparts. The E option from the main menu can help out in such cases. Once you have captured the picture you want, you can enhance contrast by a factor of 1.5 by typing E from the main menu.

When you do so, there will be a slight delay and then the E you have typed will disappear. If you type D followed by P, you can see your enhanced image. An example of a standard and an enhanced picture can be seen in Photos I and J. *Note that this routine should be used with care!* Unlike all the other routines discussed so far, it permanently changes the image in memory! If you don't like the results, you will have to reload the picture from tape to get the original version back on the screen. Also, although there is no limit to how many times you can run the E routine on a picture, the image will tend to degrade steadily after the first enhancement run. You can try additional passes through the routine if the first did not get you all that you expected, but don't say you weren't warned!

Hard Copy. One of the beauties of scan conversion is that you can view a large number of satellite pictures without piling up costs for photographic supplies or FAX paper. Obviously, however, there will be times where you would like to have a permanent copy of a particularly interesting picture. Photographing the TV display is one option, and you can use relatively economical roll film since you do not need the pictures immediately.

A second option is to use the T routine from the main menu. This will permit you to print the image being displayed using an Epson printer (MX-80 with the Graphtrax option, or the newer RX-80). An example of a full-frame printout is shown in Fig. 9. Full-frame printouts will have lower resolution than the image displayed but will be quite useful in most applications. The resolution of printouts from High Resolution 1 images is equal to that obtained with many CRT display systems. The advantage of the printer approach to hard copy is that the printer is useful in all other applications of your CoCo, so your hardware acquisition will have multiple uses.

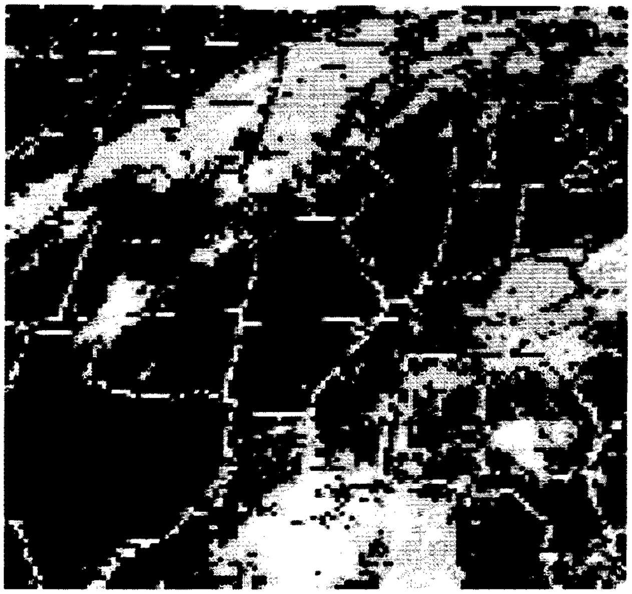

Fig. 9. An example of image printout using an Epson RX-80 printer. This is an HR-1 image from a GOES E infrared image of the United States (as in Photo A). This HR-1 view extends from Texas in the lower left to northern Florida in the lower right. Michigan is in the upper right and the US/Canadian border runs along the top. IR images display cold objects as white. The ground surface is warm and hence dark. Most of the cloud features in this view are mid-range gray, indicating relatively warm (and low) clouds. The white centers of the clouds in the Gulf of Mexico and southern Georgia indicate colder and higher cloud features.

Low-Density TRS-80C Display

Most of the remaining main menu functions that are available will not be discussed as they are more specialized and space is limited. The exception is the L routine which appears on the main menu and also on the display menu. This is a routine that will print a low-resolution, limited gray-scale version of a satellite picture directly on the TRS-80C display monitor without the use of the high-resolution display board. If you use a color monitor you should disable the color when using this option. The picture is quite crude and the routine is perhaps best used to check out the interface functions prior to getting the display board on line. This routine will not be supported with future program revisions and may eventually be dropped if other new routines have a higher priority.

High-Frequency FAX

Weather charts and almost any imaginable kind of picture material are transmitted regularly on HF (SSB) using various FAX formats. All of these have a video "swing" identical to that of SSTV—1500-Hz black to 2300-Hz white. Since HF video is identical to SSTV video, you can simply drive the CoCo joystick port with the output of the SSTV demodulator while driving the serial port with this month's interface to provide line sync. The only change in recording an HF FAX signal is to route the output of the HF receiver to the right-channel input with the right-channel output going to the input of the SSTV demodulator.

The single biggest problem with FAX is that the signal does not contain a 1200-Hz sync pulse, and since there are no intervening voice transmissions, the signal can be difficult to tune on SSB. One possibility is to wire up a pair of NE567 tone decoders with LED indicators, one tuned to 1500 Hz (black) and the other to 2300 Hz (white). The circuit values shown for U8 on the interface should do just fine for such decoders. Phasing on HF FAX usually uses one of two formats—white video with a black framing marker or black video with a white framing marker. In either case, if you tune so that both indicators flash during phasing, you will be right on frequency.

HF FAX uses several standard line rates—typically 120 but also 60 and 240 lpm. Begin by typing R from the main menu and phase the picture. You can then try keys 2, 1, 5, and 6 in sequence to see which gives the best display for the transmission in question. Once you have identified the proper key for a specific station, you should log the information for future use. Again, as in the case of satellite transmissions, recordings will let you experiment as long as desired to determine the optimum display format. Weather charts will tend to be disappointing due to the large amount of fine detail, but wirephoto transmissions yield excellent results. The press frequencies for this sort of thing are not widely publicized, but several books are available listing these and other "confidential" HF frequencies.

Parts List
(Weather-Satellite Interface)

Transistors

Q1-3, 5	2N4401 (General purpose audio NPN)
Q4	2N4403 (General purpose audio PNP)

Integrated Circuits

U1	LM1458 (Dual 741/Mini-DIP)
U2	LM324 (Quad op amp)
U3, 9, 11	SN7400N (Quad NAND gate)
U4-6, 12, 13	SN7490N (Decade counter)
U7	LM741CN (741 op amp/Mini-DIP)
U8	NE567 (PLL Tone decoder)
U10	SN7492N (Divide-by-12 counter)
U14	SN74121N (Single-shot)
U15	MC1488P (RS-232 Line driver)

Diodes

D1-7, 10	1N4001
D8	5.1-V, 1-W zener
D9	Radial mounting LED (sync lock)

Resistors

All values in Ohms. Unspecified units are 1/4 W, 5% composition or metal film. PC indicates A 1/4- to 1/2-W printed-circuit pot. Panel mounting indicates a standard panel-mounted pot.

R1	10k PC (agc threshold)
R2, 4, 32, 47	4700
R3	47k
R5, 6, 16, 21, 22, 24, 26, 29, 30, 35, 38, 39, 41, 48	10k
R7, 12, 15	56k
R8, 14	120k
R9	22k
R10, 19, 44, 45, 46	1000
R11	1
R13	6800
R17, 36	2700
R18, 23, 37	20k
R20	10k Panel mounting (contrast)
R25	1 megohm
R27, 28	2200
R31	1000 PC (black level)
R33, 34	470
R40	150
R42	5000 PC (vco adj)
R43	1500

Capacitors

Unless otherwise noted, capacitors should have a working voltage of at least 16 V. T indicates a dipped tantalum electrolytic, A an aluminum electrolytic (radial leads), M a dipped mylar™/paper capacitor, D a disc ceramic capacitor, SM a silver-mica capacitor, and MT a mica compression trimmer. All capacitance values in uF unless noted.

C1, 6, 7, 16, 26, 39	1 T
C2, 3	22 T
C4, 9, 10, 18, 19, 28	0.01 M
C5, 38	10 T
C8	100 A
C11, 12, 20, 21, 24, 25	0.1 M
C13	27-pF SM
C14	0.22 M
C15	0.047 M
C17	40- or 60-pF MT
C22	2.2 T
C23, 31, 35	4.7 T
C27	120-pF SM
C29, 30, 34	0.1 D
C32, 33, 36, 37	0.01 D

Misc.

X1	2.4 MHz at cut crystal/32-pF load/0.002%
M1	50-microamp panel meter (agc)
J1-7	Switchcraft 3501FR or other phono jack
S1	DPDT subminiature toggle (RCV/Tape)
S2	Normally-closed push-button (Phase)
S3	SPDT subminiature toggle (120/240 lpm)
S4	Normally-open push-button (Reset)
S5	SPST toggle (power if supply internal)
L1	12-14-V LED or other panel lamp (power)

The Future

The present CoCo FAX system offers extreme flexibility and excellent results. One of us (WB8DQT) has all kinds of CRT and FAX display systems but has used little but the CoCo since we got the system up and running. If new routines prove to be useful or if new FAX formats appear, they will be added to the software in an attempt to keep it as current and useful as possible. The guiding philosophy will be that inexpensive software upgrades are preferable to making extensive hardware modifications.

There is a hardware option, however, where you can expect to see developments—the display board. The basic high-resolution display board is limited to a 256 × 128 format since only 16K of static RAM is used. Despite this limitation, the FAX results are quite good as evidenced by the photos in this article—all of which were photographed from that standard display-board output. Some experimentation by K6AEP has shown that it is practical to load the display board with as much as 32K of static RAM—enough to provide a 256 × 256 display format!

By the time this article appears, Multimode and L. W. Interface will offer both versions. The 256 × 256 version is obviously a bit more expensive, but the display is capable of pushing the resolution limits of most monitors. The WEFAX Ver. 3 software has been modified (along with various SSTV options) to support either 256 × 128 or ×256 display. You can start with and stay with the first or later upgrade to the second and still use the same software.

Conclusion

Up to this point in time the differences in image formats and the equipment required for image processing have kept the various types of video experimenters separate and distinct. One of our goals has been to use the power of the 6809 microprocessor as a flexible image-processing system. With the power of a 64K CoCo, some hardware interfaces, and flexible software, the segregation of ATV, SSTV, FAX, and the weather-satellite crowd is a thing of the past—not to mention CW and RTTY! For about what you would pay for a dedicated system for any one of these modes, you can have it all!

If you stop to think that the same computer can calculate satellite orbits, keep your log, balance the checkbook, and teach the kids, we think you will agree that it will be a much easier job to sell the family on the "new" gear. Of course everything has its price. Once you are geared up you will have the terrible decision about which of all those modes you want to use when you fire up the rig! For that weighty question we can suggest only that you write a program to let the computer decide! ■

Transistors: A Biased Approach

In Part I, KC0EW takes the mystery out of solid state with clear talk and practical examples.

Sometimes I think things were a lot simpler in the "good old days"—you know, vacuum tubes and all that. Then, you could visualize the electrons happily zipping from cathode to plate, with a varying charge on the grid adjusting the flow. You even had a nice orange glow from the filament when you turned the thing on, a reassuring visual indicator that something was happening. The transistor changed all of that—now all we have to look at are little metal cans that look just the same, on or off. And the way they operate! All this talk about "electron/hole pairs" and "minority carriers." It's a miracle anything ever gets designed with these things, they're so hard to understand.

Wrong. Transistors aren't much more complicated than any other electronic device (they can be a lot simpler than tubes in many cases), but they do have their own way of operating, and once you've learned a little about it and how to use them, everything's simple.

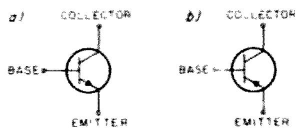

Fig. 1. NPN (a) and PNP (b) transistors.

So, let's get with it. I'm not going to cover any solid-state theory here, just how to use these things in something practical. Maybe we'll look at the theory some other time.

Your basic, garden-variety bipolar transistor has exactly three leads—emitter, collector, and base. You can find which is which for the particular part you're working with by checking the data sheet, but all transistors share two basic properties in normal operation. First, the current flowing from collector to emitter is some multiple of the current flowing into (or out of) the base lead. Second, the voltage drop across the emitter and base is constant. This applies only when operating in what's called the "active" mode, but we'll get to that in a moment.

Fig. 1 shows the two types of bipolar transistors: the NPN, (a), which is drawn with the arrow on the emitter pointing away from the base, and the PNP, (b), drawn with the arrow pointing in. As a general rule, anything you do with one, you can do with the other if you swap all your polarities—a positive supply becomes a negative supply, etc. Fig. 2 shows this. Here, the two transistors are shown with voltages set up between the three leads to put them in the active mode. (Properly arranging the voltages, currents, or whatever on a transistor or any other device is called "biasing," and that's what this article is all about.) For the NPN transistor to be active, the collector must be more positive than the base, which in turn must be more positive than the emitter. The PNP is just the same, but here the collector is more negative than the base, and so on. We'll limit our discussion to the NPN, but remember that everything will also apply to the PNP—just turn the voltages and currents around.

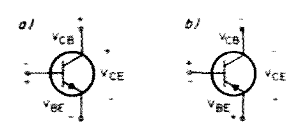

Fig. 2. The NPN (a) and PNP (b) transistors biased for the "active" mode of operation. Note that the only difference is the polarity of the voltages.

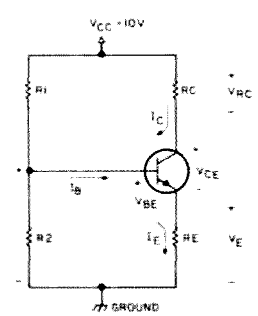

Fig. 3. An NPN transistor with a network of resistors for biasing.

The active mode of operation is the one most often used in linear circuits such as amplifiers, and in this mode the transistor is indeed acting as an amplifier. The current flowing into the collector lead is directly proportional to the current into the base lead. The other two modes possible are "cutoff" and "saturation." Cutoff is exactly what you'd think—the transistor is turned off and no current flows at all. This occurs when (for the NPN) the base is less positive than the emitter. Saturation occurs when the base is more positive than either the collector or emitter and means that the transistor is passing all the current it can for that particular biasing. (Note that saturation *does not* mean that the transistor is carrying its maximum rated current, only that it's carrying all that's possible for that particular setup.)

There's another way to look at the modes of operation we've just discussed. The transistor can be viewed as two diodes, one from base to emitter and the other from base to collector. (You can see it in the names

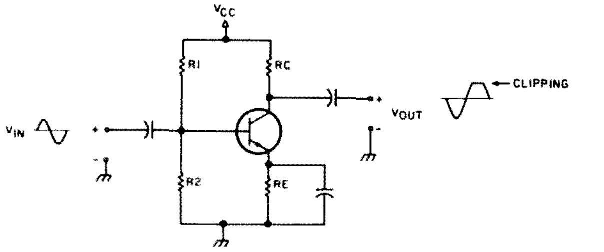

Fig. 4. A simple transistor amplifier. If the dc level at the collector is too high for the signal level expected, the output may clip as it tries to exceed the limit set by the supply voltage (Vcc).

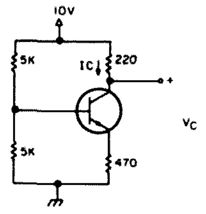

Fig. 5. The NPN transistor with some values for the biasing resistors. Ignoring beta, this circuit gives Vc = 8 V and Ic = 9.2 mA.

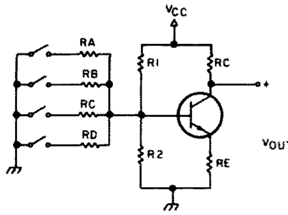

Fig 6. A simple digital-to-analog converter (DAC). As various resistors are grounded through their switches, the voltage through the base, and therefore the output voltage, changes.

NPN and PNP—two P-N junctions, or, in other words, diodes.) A transistor is active when the base-emitter diode is "forward-biased" (positive on the P side and negative on the N side) and the base-collector diode is "reverse-biased" (positive on N, negative on P). Either way, you can tell how a transistor is operating just by figuring out how the voltages are arranged around the three leads.

Fig. 3 shows an NPN transistor along with four resistors which we can use to establish the "dc operating point," in other words, to bias the transistor for proper operation. The dc operating point is usually specified in terms of the collector current and the collector voltage when no signal is applied. It's important because it will affect the operation of any circuit we build with the transistor.

For an example, let's suppose that the transistor is being used as an amplifier, as in Fig. 4. With the supply voltage (Vcc) at ten volts, the collector voltage will determine how far the output can swing before clipping. If, say, the collector is at 7 volts, we'd better not expect to get a signal out that swings any more than 3 volts positive—if it does, it'll run into the limit of the supply voltage and clip. This isn't the only way the operating point is important, but you can see that it's not something to ignore. On to biasing.

Remember the two points I made earlier: that the voltage drop from base to emitter is constant and that the current flowing in the collector lead is some multiple of the base current. The number you multiply the base current by to get the collector current is called *beta*. This may also be given as the Greek letter, β. Both of these will affect the operation of the transistor in any circuit, but beta is usually the more difficult of the two to handle. Not only will beta vary from part to part (sometimes by as much as five to one or more), but even the beta of a given transistor will wander around as the temperature, collector current, etc., change. Designing for a stable operating point for varying betas is really what biasing is all about. Now, some *practical* examples:

For our first try, we'll ignore the base current of the transistor and thereby ignore beta. This really isn't such an unreasonable thing to do since if beta is high enough (and most small-signal transistors sport a beta of at least 100), the base current really is negligible compared to the collector current. We'll use the NPN with a resistor network for biasing, as shown in Fig. 3. Now, if we ignore the base current, we can very quickly get some expressions for the currents and voltages in this circuit.

The point we're interested in is the collector—we want the voltage at the collector and the value for the collector current which is flowing through Rc. Obviously, by Ohm's Law, there must be a voltage drop across Rc of VRc = Ic × Rc, so the voltage at the collector is just Vc = 10 V − VRc. The emitter current must be the same as the collector current (we're ignoring the base current, remember?), so the voltage at the emitter (the voltage across Re) is VRe = Ic × Re.

Wait a minute! If the drop from base to emitter is constant, then the base will always be a certain amount more positive than the emitter. This drop is around 0.7 volts for a silicon transistor, so Vb = Ve + 0.7. Again, we're ignoring the base current, so Vb may be determined easily—R1 and R2 are just a divider, and Vb = 10 × R2/(R1 + R2).

Working backwards through the relations we discovered above, we can get the collector current (same as the emitter current) as Ic = ((10 × R1/(R1+R2)) − 0.7)/Re.

Fig. 5 shows the same circuit with some values for the resistors. Using the above formulas, we can find the voltage at the base to be Vb = 10 V × (5k)/(5k + 5k) = 5 V and the voltage at the emitter to be Ve = 5 V − 0.7 V = 4.3 V. The emitter and collector currents are then Ic = Ie = 4.3 V/470 = 9.2 mA and the collector voltage must be Vc = 10 V − (9.2 mA × 220) = 8 V.

If you build this circuit (any small-signal silicon NPN should work), you should measure voltages very close to the ones we just calculated. As a matter of fact, just using this type of analysis can allow us to design a practical circuit.

What would happen, for example, if we could switch the values of R1 and R2 around at will? One easy way to change this divider would be to put other values in parallel with R2, which will lower the resistance from base to ground. We might do this as shown in Fig. 6, with several different resistors tied together at the base and then individually switched to ground. A resistor whose switch is open would simply "float" and make no difference to the circuit whatsoever. Switching different combinations of resistors in and out would vary the voltage at the collector. If we chose the values of these resistors properly, we could use this circuit as a digital-to-analog converter, or DAC. DACs are used extensively to allow digital circuits, such as are found in microcomputers, to control analog voltages.

Fig. 7 shows a practical version of this simple DAC. As the binary representation of the numbers 0 to 15 is fed into the 74LS05 (a 7405 or 74S05 works just as well), the output (at the collector) will change in even steps from a maximum to a minimum value. If the DAC is driven by a counter, such as

the 74LS163 shown in Fig. 7, the process will repeat over and over again and the output will appear to be a "sawtooth" wave. With the values shown, the maximum voltage at the output will be around 10–11 V and the minimum 2–3 V. (These will vary somewhat due to part tolerances and variations in the base-to-emitter voltage.) The 555 timer provides the clock for the counter, here at about 16 kHz. The output frequency will be 1/16 of this value, or about 1 kHz.

If you build this circuit and have access to an oscilloscope, be sure to look at the signal on the base when the counter is running.

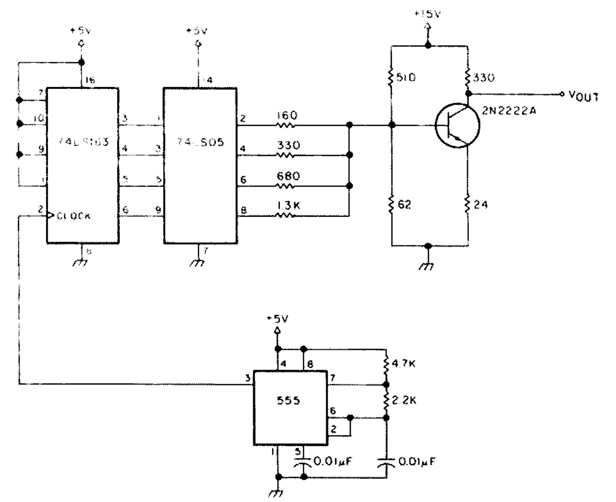

Fig. 7. The DAC used to generate a "sawtooth" waveform.

Notice that it appears to be a smaller, inverted version of the sawtooth waveform seen at the collector. Surprise! The transistor is really acting as a simple amplifier, taking the small signal we've made at the base and making a bigger copy of it at the collector. (The inversion of the signal is characteristic of this type of amplifier.)

You may want to try your hand at designing one of these yourself. First, a word of advice: This is never going to be a very classy way to make a DAC, and variations in the resistors or the transistor itself can, as noted above, cause the output to change from the designed value by quite a bit. But it's kind of fun to try these things for yourself, so here's how.

The 7405 is an inverter with "open-collector" outputs. This means that the output pin is simply the collector of a transistor, and when an input is high, this transistor is switched on and effectively takes the output (the collector) to ground—the transistor, in other words, saturates. It won't actually make it all the way to zero volts—there will always be some small drop across this transistor, around 0.2–0.3 V. We can assume about 0.25 V for the purposes of this design. Thus, a high input will pull the resistor associated with that bit to 0.25 V. The drop across the resistor is the base voltage minus 0.25 V. We start by setting up Re, Rc, R1, and R2 for the desired minimum output voltage at the collector. In this stage of the design, assume that all of the "extra" resistors are floating—they can be ignored.

With the minimum voltage established by the basic biasing network, we can add the extra resistor to pull the base voltage down and so increase the collector voltage. If you want to use a straight binary input such as the one shown here, calculate the value of the smallest resistance (the most significant bit of the input) first. This may be done by figuring what the base voltage needs to be for an output voltage that's halfway between the desired minimum and maximum—this *is* the most significant bit, remember? Given this voltage, the current through R1 is found by subtracting this base voltage from the supply and dividing by the resistance of R1. Since we're ignoring the base current, the sum of the currents through R2 and Ra must equal the current through R1, and so we find the current in R2 next. This is simply the desired base voltage divided by R2. Subtracting this current from the current in R1 gives the current that must be drawn by our most-significant-bit resistor, Ra. The value of Ra is just the drop across Ra divided by this current, or Ra = (Vb − 0.25)/Ia.

The remaining resistors may be calculated in a similar fashion, or for a straight binary DAC, each resistor will be twice the value of the one for the bit to the left. If we want a four-bit DAC, such as the one shown, and we calculate Ra to be 500 Ohms, then Rb = 1000 Ohms, Rc = 2000 Ohms, and Rd = 4000 Ohms. Use the nearest value available and use the most precise resistors available for best results.

With this example, we've learned in a very basic way how the transistor may be biased to provide various desired levels at the output and even found a way to get it to act as a simple amplifier. But we haven't covered what's really going on with a bipolar transistor—the control of the collector current by changing the base current. In Part II, we'll look at this action and work beta into our analysis of just how this little piece of silicon acts. (Thanks to Richard Herrington for the suggestion for the DAC circuit.)■

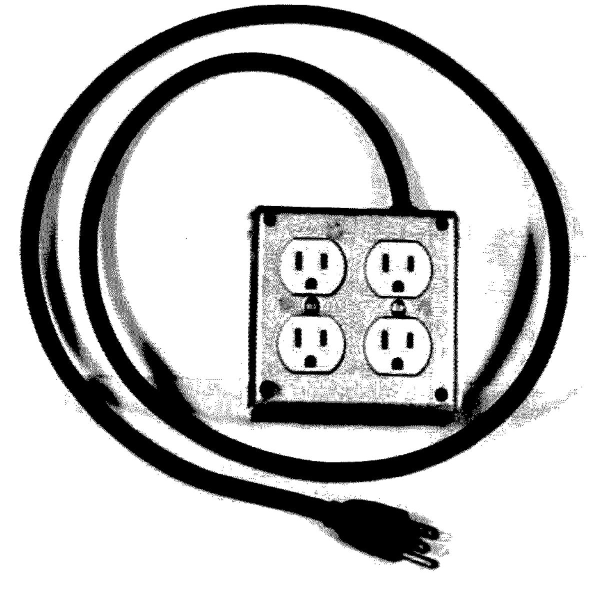
Yikes! Spikes!

You paid good money for that computer system. Now spend a few hours building an insurance policy against voltage spikes.

How many of you computer users are aware of the damage caused by voltage spikes present on the ac line? These little gremlins can scramble programs and destroy sensitive ICs. Commercial filters are available to alleviate these problems, but their cost can often exceed the price of your computer! So if you cringe every time the refrigerator turns on, or if you are unaware that this potential problem even exists, please read on. A little solder and an evening's work will produce a filter that will protect your investment at a fraction of the commercial cost.



This unassuming device could save you thousands of dollars.

Description

This filter will protect your computer from two types of interference: line transients and RFI. Transients have many sources. Inductive loads, such as motors turning on and off, will generate voltage spikes on the ac line. These spikes can be many times higher than the nominal 117 V ac. A nearby lightning strike can also cause a spike. Even turning your printer on or off can create a voltage spike. A subtle result of these transients can be information scrambled in the computer's memory or, more seriously, blown IC chips in your equipment.

To prevent these spikes from damaging devices on the ac line, three metal-oxide varistors (MOVs) are used. This device is a voltage-dependent, symmetrical resistor which acts like back-to-back zener diodes. The MOV normally presents a high impedance across its leads. However, when a voltage spike is present, the impedance of the MOV becomes very low, providing a conducting path for the spike energy. The MOV can handle surges of up to 4500 Amps at 175 volts. An MOV is used across the line and from each leg of the line to ground. This will shunt damaging spikes away from sensitive equipment.

One word of caution is in order here. An MOV that is exposed to an extremely high energy pulse can overheat and shatter. You could protect each MOV with a ten-Amp fuse in series with it, or omit the fuses and house the MOVs in a box to protect yourself in case of this unlikely event. I chose to allow the MOVs to self-destruct in their duty of protecting my equipment. An

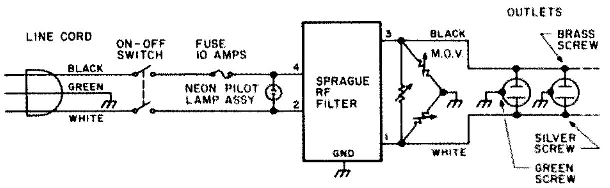


Fig. 1. Schematic diagram of the filter.

Parts List

Metal-oxide varistor	RS 276-570	3 @ $ 1.59
Rf filter, 2 × 12 Amps @ 250 V ac	Sprague JN10-2296A1, from Fair Radio Sales Lima OH	3.95
Line cord	W14-3CG, from Fair Radio Sales	2.00
Pilot lamp assembly	RS 272-707	2.19
DPST switch	RS 275-1546	2.69
10-Amp fuse holder	RS 270-739	.79
4" × 4" × 3" metal box	hardware store	1.69

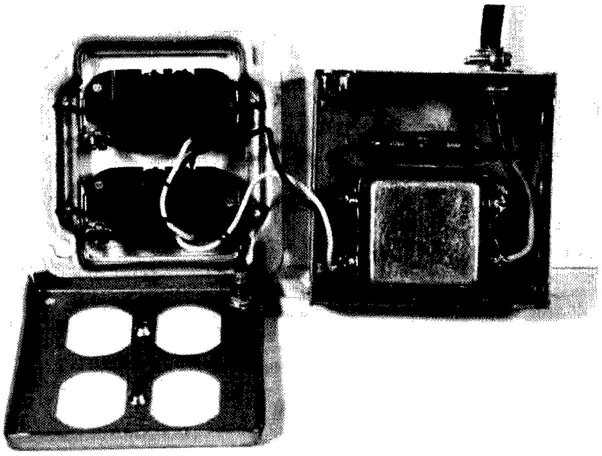
Romex connector	hardware store	.20
Duplex outlets	hardware store	2 @ .39
Outlet cover	hardware store	.99
		$20.44



Inside the filter. The outlets are mounted on the box extension.

MOV is still far cheaper than my computer.

Computers are also affected by radio-frequency interference, or RFI. Rf energy can enter the ac lines from your transceiver, a nearby lightning strike, or your neighbor's CB set. This stray rf can also wreak havoc with computer operation. Likewise, computers generate quite a bit of RFI themselves. This can show up as noise on your receiver or television set. An rf filter takes care of RFI coming *and* going. A commercial rf filter available at a very reasonable price is used. It is rated at 12 Amps, which is well above my modest current draw. In my case, a very poor picture on my monitor was completely cleared up using this device.

Construction

I housed my filter in a 4" × 4" × 3" metal box used in house wiring. A box extension, or "mud ring," is added to the front of the box so that the outlets will clear the rf filter. The filter and the fuse holder are mounted on the bottom of the box using 4-40 hardware. A Romex connector is used as a line-cord strain relief. The MOVs are soldered directly to the rf-filter terminals. The duplex outlets are screwed directly into the box extension. All of these details can be seen in the photographs. Since the filter is capable of handling 12 Amps, number 14 or larger wire should be used throughout.

For the best protection and for safety's sake, the green wire (grounding wire) must be *securely* fastened to the metal box. DO NOT OMIT THIS! If something should happen and a live wire comes in contact with the metal box, the green wire will cause the fuse to blow. Don't let sloppy twelve-volt construction habits leak in. This is 110 volts ac and can be *deadly* if mishandled. Likewise, the ground screws on the outlets and the rf-filter ground should also be securely fastened to the box. If your house still has the older two-wire outlets, I suggest building this filter in a plastic insulated box to eliminate any shock hazard.

Also, pay close attention to the black and white wires of the line cord. Be *absolutely sure* that the proper color wire of the line cord makes it to the appropriate screw of the outlet. The white wire should eventually end up under the silver-colored screw of the outlet. The black wire should end up under the brass-colored screw. Don't get your wires crossed! If you have any doubt, consult your local electrician. Using the schematic, wiring should take but a few minutes.

Checkout and Operation

Using an ohmmeter on the high range, measure the resistance between each of the two pins on the outlet and ground. The reading should be infinite. The reading between the two pins of the outlet should also be infinite. Next, measure the resistance between the ground pin of the outlet and the case. The reading should be zero. Finally, check for continuity between the white wire of the line cord and the silver screw of the outlet. Ditto for the black wire and brass screw. Make sure that these wires are not crossed!

Your computer and disk drives should be plugged into the filter. Your monitor and printer should be plugged directly into the wall outlet. That's all there is to it! Now, when an unannounced spike arrives at your door, simply shrug it off and keep on computing.■

Roland IA 50236

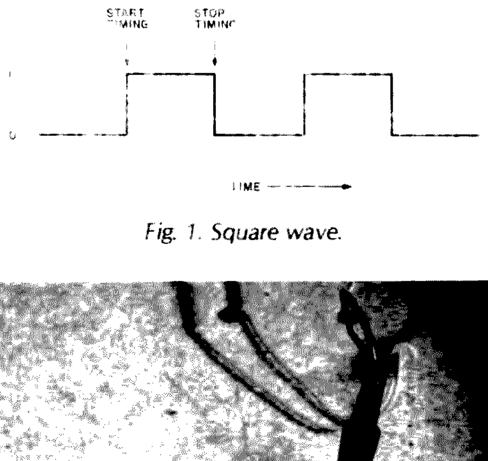

Fig. 1. Square wave.

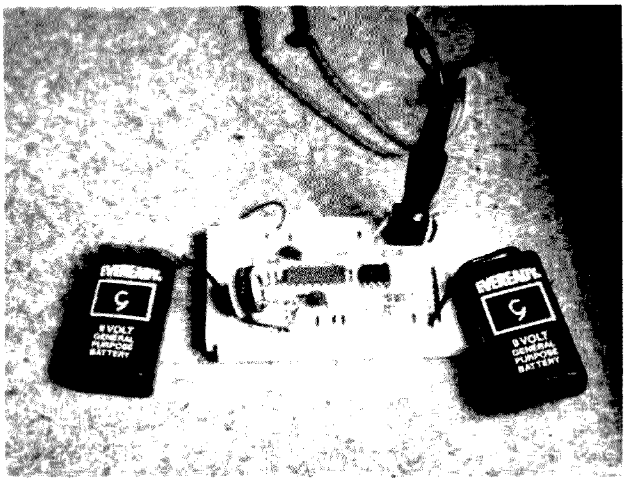

The completed unit.

Home computers are used for many applications, from balancing checkbooks to defending civilization from the Klingon Empire. All of these programs have a common characteristic: Important data must be included in the program itself or entered from the keyboard. Manual data entry is tedious for long lists of data and impossible for voltages and other analog measurements that occur in real time.

The usual method of entering an analog value into the computer is the analog-to-digital integrated circuit (A/D) which converts a voltage to a digital word that can be read by the computer. This approach has several disadvantages. First, a rather complex integrated circuit is required to do the conversion. Second, the output of the A/D must be passed on to the computer through an 8-bit I/O port, which requires another complex IC. Third, the expansion bus on the computer is tied up with the I/O port and is not available for other applications (such as a RTTY terminal).

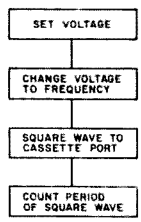

Fig. 2. A/D function flowchart.

The advantages of A/D circuits will be discussed in the conclusion section of this article. The capability for a simple A/D converter can be implemented on the TRS-80™ Model III microcomputer using only two ICs and the cassette port. The remainder of this article will describe the basic approach used and the hardware and software to construct a simple computer voltmeter.

Basic Concept

The cassette port on the Model III TRS-80 microcomputer is available as an input

Program listing 1.

or output device and can be accessed with the Basic command INP(x) or OUT(x). The data obtained from the cassette port is in binary format, that is, either a 0 or a 1, seemingly not very useful in measuring an analog signal. However, if the signal into the cassette port is a square wave, as illustrated in Fig. 1, then more useful data can be obtained.

If the time that the input port is in the 1 state can be measured, then the period (P) of the square wave (and frequency, since f = 1/P) can be determined. To use the cassette port to measure a voltage, the signal must be changed to a square wave with a frequency that is proportional to the voltage. Fortunately, an integrated circuit exists, the 9400 V/F converter, which is designed specifically for that function. The concept used to implement the A/D function is given in flowchart form in Fig. 2.

Hardware

The circuit that performs the hardware functions of the simple voltmeter is shown in Fig. 3. The heart of the system is the 9400 voltage-to-frequency (V/F) converter. This chip can be wired for a variety of applications including V/F, F/V, a frequency-shift keyer, and more. In this application, the input voltage is converted to current by the input resistor and sent to pin 3. The output at pin 10 is a square wave of about 50 mV. This signal is boosted to approximate TTL (0-5-V) levels by the first section of a dual-741 operational amplifier. The second section is used to produce a waveform symmetrical about zero, which is required by the Model III

Program listing 2.

cassette-input circuitry. The 100k-Ohm potentiometer is used to provide an input voltage for testing or offset.

Any construction technique should work as long as neatness and minimum-lead-length guidelines are followed. Two 9-V transistor batteries are used for the power supplies and should provide many hours of operation. One disadvantage of the 9400 IC is that the input voltage and output frequency are related by a power curve. This problem can be solved by using software.

Software

The programs needed to implement the computer voltmeter are straightforward. A short machine-language routine that counts the period of the square wave is given in Program listing 1. The important parts of the program are the two loops, marked by STATE1 and STATE2. The first loop waits until bit 0 of port FF (the cassette port) changes state. The second loop tests the port for the same condition but increments a counter before each test. The final count is passed back to a Basic program using a statement such as A = USR(x).

The Basic Program listing 2 first POKEs the machine-language program into the top of memory (48K machine) and sets the disk Basic USR address. For a 16K non-disk system, the following lines should be changed:

```
20 FOR I=16351 TO 16380:
READX:POKEI,X:NEXTI
50 POKE 16526,223:
POKE16527,63
300 A=USR(X):RETURN
```

Don't forget to protect the upper memory before running the program (use a value of 65400 for the disk version and 16300 for the 16K version).

The relationship between the measured period and the input voltage is nonlinear and follows a power curve, that is, a function of the form: period = a*(voltage)exp(b).

The program starts out by acquiring a number of calibration points. The voltages can be obtained using the potentiometer shown in the circuit diagram. The best results were obtained when calibration voltages were from 0.5 V to 2.5 V in about 0.25-V increments. Line 220 prints the constants on the screen and lines 230 to 270 are used to calculate an unknown input voltage.

Since the V/F relationship is a power curve, voltages at the high and low ends of the 9400's range are not measured as accurately as values in the middle of the range. When input voltages were held to the range mentioned above, measured unknown voltages were within ±10% of the actual values. Input voltages can be kept within those limits by adding a 0.5-V offset voltage to the input (using the potentiometer) and limiting the input to 2.0 V using voltage dividers or operational amplifiers.

Conclusion

By no means is this circuit designed to be a high-accuracy A/D. The main thrust of this article has been to illustrate how an A/D converter can simply and with very little effort be added to a computer system. The nonlinear response of the system limits its accuracy. Traditional A/D converters are linear, provide better accuracy, and can be much faster.

This is not to say that this application is worthless! The number of potential applications is limited only by the imagination. For example, the output of a weather station could be monitored and weather data plotted out. The system also will provide a useful addition to the computerist who wishes to dabble in hardware interfacing. ■

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 4

And remember that with Reagan boss for four more years, we have to live with the mess we've made. And we've made the mess, not the FCC.

The Commissioners were right in their perception of the problem and probably right in their attempt to solve it. They just couldn't conceive that the League could be so blind as to destroy the hobby rather than let it grow.

I've talked with most of the Commissioners at length and what has happened is not the result of any misunderstanding. They understand amateur radio better than most amateurs and my hat is off to them for doing their homework.

They recognize that today amateur radio is no longer providing the services for which it was chartered (see 97.1). They see it, all too clearly, as a small elitist group of aging men, largely retired, who want to preserve their fun and keep newcomers out.

They know our incredible past record of inventing and pioneering new modes of communications, but they also know that this aspect of the hobby died out twenty years ago when the League proposed to take away phone privileges from 85% of the hams.

For twenty years the hobby has lived on its old glory. Now amateur experimenting and pioneering are virtually dead. Indeed, this is the realm of the younger ham, not the old-timer, and we have almost no young hams these days. Just go to a hamfest or a club meeting and you'll see for yourself.

The lack of youth on our bands has helped to develop cliques among the old-timers. Today we hear foul language on our bands that was completely unknown twenty years ago. We hear organized groups of jammers on service nets and repeaters. Indeed, you'll be hard put to find CB anywhere in the country as bad as some of the stuff we hear on our ham bands.

Complaints to the FCC? Make me laugh! They now taunt us with our once proud claim of being the number one self-policing radio service. Old men don't seem to have much fighting spirit, so when another cranky old man gets on the air and louses it up, the first old man just turns his rig off and calls the FCC, only to find they really don't care. Youngsters would get their bile up and make it their business to do something about it.

How many of you reading this can remember when you had pride in being an amateur? We were damned good communicators! We built ham gear and we had a ball. I built my first narrowband FM rig back in 1948 and helped pioneer that new mode. I got fascinated by digital communications then and built my own RTTY equipment. *73* was founded on the basis of helping hams to design and build new equipment—to cope with the changing technology. We were in there first with SSB and then with solid state. What magazine made repeaters happen as a world phenomenon? If you don't know, it was *73*, and with zero help from any other magazine.

Now what do we build? What have *you* built lately? Are *you* on OSCAR? Are *you* on RTTY? Packet radio? Are *you* going to try spread-spectrum?

Sure, there are a few old-timers who have devoted their lives to getting QSL cards from over 300 countries. A fat lot of karma in that! What a waste of a life! That's no more valuable than going to your grave knowing the ratings of all the major-league players. Phooey.

Good karma? There's lots of it around. Just get some youngsters into our dying hobby, that's all. I've been to a couple of ham clubs recently giving talks and they were proud that they had chased all of the kids out. Bunch of old men all agreeing that no one should get a ham ticket without the code, yet most of 'em bitterly oppose any move to check to see if they still remember the code, which many don't.

Can your bunch of old fogies get a ham club started in a local high school? Wait until you hear all the excuses from OMs too busy for that.

No, the Commissioners were right on the beam when they decided that amateur radio had outlived its usefulness. Unless you personally do something which will help to change what is happening, all you are going to see for the next few years is one ham band after another going away.

Put yourself in their seat. Would you squander a public resource worth billions on a bunch of old men who are using it for a useless hobby? Heck, we aren't even a major market for ham gear—most of which is being made in Japan these days. We're just making the balance-of-payments situation worse.

Shall we have a short commemorative prayer for Hallicrafters, Hammarlund, Johnson, Gonset, Central Electronics, Harvey Wells, Webster, Swan, Galaxy, WRL, Sideband Engineers, Eldico, and Lakeshore Industries?

We haven't invented anything in twenty years. We are no longer of value as a source of trained technicians for the military in time of war. Tell me about international friendship—that is, if you can take your hand off the mike button in that pileup for a moment.

You, on the repeater, would you mind telling me again where you are located? That was the high point of your endless transmission and I was dozing off when you mentioned it—just before the jammer with the boring supply of four-letter words broke in.

I'm trying to get high-tech hobby clubs started in high schools. I've donated groups of computers to two local schools and they are both going great guns. High-school ham clubs don't even need equipment—all they need is encouragement and to have local hams come in and teach them the code and theory. They need a weekly meeting and pep talks about the excitement of the hobby. I'm involved in my town; how about you? Too busy?

Oh, I'm working on the national level, too. I'm on the advisory group for Senator Humphrey, I talk with the FCC Commissioners, I talk with Senator Gold-

water, and so on. How about you? Have you ever visited your Congressman and asked him to help get ham clubs into every high school in your state? Have you discussed this with your governor? I've talked my governor's ear off on the subject, and he's very interested. I've also talked with the governors of Vermont and Maine. How about you? What are *you* doing?

You'll find politicians interested in your ideas. They are so used to pressure groups coming to them demanding government support that someone asking for something which costs nothing is a novelty.

So there you have it. If you'll devote 5% of your hamming time to interesting youngsters, to getting a ham club going in your local school, to talking with your governor, congressmen, and senators, we could have our hobby moving ahead in a couple of years. If you don't, it could easily blow away in the same time.

Do you really think that the major communications firms are not well aware of how weak we are? They can make billions using our channels, so you better believe that this has their attention and that they are willing to spend whatever it takes to get rid of us.

It's up to YOU.

LETTERS

TV VIEWERS NOT DOERS

This is in response to your July, 1984, editorial on implementing a period of instruction time devoted to a "high-tech hobby club, amateur radio, computer, astronomy, whatever." You are implying that by simply getting our teenagers to participate in high-tech pursuits we could get the good ol' US of A back in step with the Japanese.

I agree with you that we must get our youngsters more interested in a field of science that would contribute to America's technological pool. But you can't expect American kids to get involved on the same level as the Japanese kids—mainly because they have a more effective educational system and American kids are more concerned over spending their time having fun rather than figuring out new ways to implement high-speed digital communications.

How many times have you turned on your TV set just in time to catch a bunch of beach-going teenagers advertising some soda pop, bubble gum, acne medicine, clothing, etc., all having a great time? (Or do you have time to watch the tube?) No wonder the American teenager is what he/she is today, a product of a society that seems to encourage having a good time, all the time. I guess having fun comes with the territory when you live in a prosperous nation. But so do the Japanese; how come they don't have the same problem? What have I been discussing for the last two paragraphs?

I am the trustee of an endangered species—a high-school ham club in the US. We are a newly-born organization, only two semesters old. I put notices in the campus bulletin, which is read every school day, a full semester before our club started, only to have the massive number of six students show up for our first meeting (three of whom stayed on, bless their hearts). We hold our meetings once a week after school for the reasons you mentioned in your editorial, lack of school support and money. I have donated much of my time and money, as well as my backup rig to the school station. I wrote several letters to major manufacturers of ham gear asking for donations of new, old, used, or repairable rigs, only to have one manufacturer reply saying how sorry they were that they couldn't help us. It is no wonder that amateur radio at the high-school level is almost nonexistent. We get no support from the school system or the private sector, and to top it all off the kids just aren't interested.

With that, I wish you better luck than I had in trying to interest our teenagers in a high-tech pursuit.

Trustee, Amateur Radio Club
Mira Mesa High School
San Diego CA

LET'S FIGHT ABUSE

This evening I sat down to talk to my friends on 75 meters. Hoping for a pleasant time with a bunch of nice people, I was shocked by what happened. Some other people felt that we were conducting our QSO on "their" frequency—not an unusual situation. But before we could get anything resolved, we were showered with a torrent of abuse. Our colleagues managed to cover a broad spectrum of bigoted obsessions: easterners (actually we cover about a quarter of the country); the ARRL (about half of us are League members); the FCC (we do have licenses); the aged (we range from 21 to 80); Jews and Catholics (we represent all major groups, including clergy and agnostics); we also include a long list of racial and ethnic groups. We were accused of technical incompetence (actually a number of us are EEs) and general stupidity (several of us have doctoral degrees). And on it went.

Most of us scattered. I stayed on, trying to talk with these people. I hoped that if they met one of us as we are, they might be less likely to attack us as stereotypes. But this was not to be, for they gave me neither a reply nor even a callsign. And not long after, they left. It was as though without us there to abuse, they had no reason to be present themselves.

Of course, I was angry. I get on the air to get away from all this. I work as a psychiatrist in a children's hospital, and I often see abuse, rejection, and hatred. I suppose, as I must sometimes tell my patients, that there is no perfect escape. Still, it hurts. Like most feeling people, when I hear this abuse I become a member of all the groups being demeaned. I wish these bigots could realize how much pain their vitriol causes. Perhaps then, if they still possess some scintilla of humanity, they would desist.

Finally, I was and am concerned. This type of bigotry, which festers in certain segments of our bands, is a disgrace too few of us wish to acknowledge. I wonder what would happen if certain civic or political leaders, say an FCC Commissioner or two, were to overhear these antics. It might be hard for us to convince them that these operations represent only a small portion of us, that they are at variance with our hallowed traditions of fraternity and goodwill.

The real world has become much less acceptant of this garbage, much less willing to look the other way. Likewise, we amateurs, both as individuals and as members of our organizations, must summon the courage to recognize this problem—and to fight it.

William M. Klykylo, MD WA8FOZ
Cincinnati OH

STIRRED UP BY WAYNE

I don't recall ever having written a letter to an editor (or senator or whomever) before. However, as you say in your September, 1984, editorial, you like to move people off dead center. Well, I really don't know if I was on dead center, but you have caused me to do some thinking, which is what you like people to do, Wayne.

Anyway, the editorial speaks to the youth of today and, again, why you think there should be a no-code license. I saw a letter in the July *QST* hitting you again on this subject. Up until your September editorial I have held the opinion that the code should be kept, even though I am one of the ones that has trouble reading the code. I have kept my speed to my license level (Advanced), and although my brain does not seem to convert the code very well to the pencil, I am determined to get that Extra! But you see, Wayne, I now have a ten-year-old son and I have not been able to interest him in radio to any great extent. I have not pushed because I do not want to force an issue and totally lose. He's mildly interested, but at his age I was an avid BCL/SWL begging every Christmas for a "better radio." I finally got a used S-20R after many requests.

You went on talking about why you think the youth of today are not interested in radio, and I think you are right! But, sad to say, I don't have any suggestion either on how to turn even my own son around. My wife and I will do the best we can. We have none of the external problems you mention; it's just the way the youth of today seem to be.

As for the code and the Japanese, I now think maybe we do have need for another class of license for the youth. We also need to have a bit faster processing of the new licenses, as well. Back in 1954 I almost gave up waiting for my first ticket, and with all the computers, one would think the process would have been speeded up in the past 30 years. I don't think there should be any reason to take more than a week to get the first license from the FCC or whomever. I also think that we should have a spot in the HF range for them to get their feet wet—maybe 10 or 15 kHz on 80 meters.

Wayne, I haven't always agreed with your editorials or the way you keep digging up old bones about *CQ*, but I must admit you moved me off dead center. I haven't subscribed to *73* since the mid 70s when prices got out of hand. However, enclosed is $19.95 for my next 13 issues.

Do me a favor, keep the ARRL on their toes but bury the hatchet with *CQ*—it's the first one I got as a new ham, reading Wayne Green, and I still get it; it's a good rag and I enjoy it every month. I also get *Pop Comm* and I enjoy every page of that, also. I don't see them still at your throat (in the mag). But do keep us thinking. I feel Wayne Green is important to the amateur community. 73.

Baltimore MD

DOESN'T MIND MONEY

I like your editorials! Not short, but certainly pointed.

Perhaps other publications of interest to amateurs ought to have a rambling editor; your column certainly allows for some steam-venting.

Anyhow, one point which you have made several times over the years is, I believe, more valid than ever—that is, the dearth of people connected with and participating in the exciting hobby of amateur radio who miss opportunities to turn their hobby into, you guessed it, MONEY!

More and more, amateurs in this country are turning into operators who know very little of the equipment they use—nor are they interested in learning the barest fundamentals of "all this fancy stuff."

'Tain't fancy at all! Same basic ol' circuits which have been around forever simply packaged in new packages. Smaller doodads doing exactly the same job as ever!

I have been a ham since my freshman year in high school (1953) and only recently has this "ignorance principle" turned itself into money.

It dawned on me that (1) there is still a lot of tube equipment still in use, (2) even more "new stuff" is coming on line, and (3) fewer and fewer hams repair anything.

With those astounding ideas in mind, a fairly broad technical education to back me up, and a few bucks invested here and there, I cranked up my money machine!

Gratifying, that, even operating part-time; there is a steady stream of broken things through the door, but it is *very* disturbing that there is little interest shown by hams in learning the technical aspects of their rigs!

I certainly don't *mind* putting their money in my jeans, but whatever happened to the roll-it and fix-it philosophy?

It is easier than ever to build quality equipment; sure the corner electronics-ham-parts place has largely vanished, but dear me, there is a veritable ocean of parts available by mail or from surplus!

Our society (even ham radio) is smack dab in the middle of a technical revolution, and no one seems to be heading for the action!

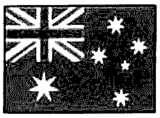
I may never become filthy rich, but I'm sure having a hell of a lot of fun! (Also forces me to say state-of-the-art!)

Robert Hall W6BSH
San Francisco CA

73 INTERNATIONAL

Each month, 73 brings you ham-radio news from around the world. In this collection of reports from our foreign correspondents, we present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to your country's correspondent or to 73: Amateur Radio's Technical Journal, *Pine Street, Peterborough NH 03458, USA, Attn: Perry Donham KK2Y.*



AUSTRALIA

J. E. Joyce VK3YJ
44 Wren Street
Altona 3018
Victoria
Australia

HIGHLIGHTS FROM THE YEAR

Following are some of the highlights from over the last year or so with amateur radio in Australia, as stated by Mr. Bruce R. Bathols VK3UV, the 1983 WIA Federal President, in his report on the 1984 Federal Convention:

- The new Radio Communications Act was passed in both houses of Parliament (as of the date of this report, we are still awaiting the Act to be Proclaimed).
- An extra 28% tariff duty was levied on *all* amateur HF transmitting equipment.
- Then, the WIA successfully negotiated a new tariff bylaw to enable the import of HF, VHF, and UHF gear at a levy rate of only 2%.
- With respect to the new tariff bylaw provisions, the WIA has been appointed the overseeing body in determining the validity of transmitting equipment as coming within the scope of the new bylaw.
- The Federal President, Mr. B. R. Bathols VK3UV, and Dr. D. Warlaw VK3ADW attended the NZART Convention in Dunedin, New Zealand, in June, 1983. Our representatives returned with a wealth of information and saw the continuing need for constant liaison to be maintained between the two amateur groups.
- Phone-patch facilities were agreed to by Telecom. On the surface all appeared OK as far as amateur radio was concerned, but in depth there are several anomalies to be overcome. At least the matter has received some attention, and the WIA is continuing negotiations with the relevant authorities.
- *Amateur Radio* magazine continues to maintain its previous high standard; much support has been received from members. *AR* celebrated its 50th anniversary during the month of October, 1983, with a special edition.
- The WIA is fortunate to have had a representative at several meetings of the Standards Association of Australia (SAA) during the year, when matters of concern to the Amateur Service were under discussion.
- As well as the above, the Institute has (a) successfully negotiated for the return of 50.000 to 50.150 MHz to the Amateur Service, as a first step towards the return of the full 50.000-to-52.000-MHz segment; (b) provided input to the DOC for the *Interim Handbook for Operators of Stations in the Amateur Service*. The WIA is monitoring progress of the Radio Communications Act, ensuring involvement in discussions about drafting regulations pertaining to the Amateur Service; (c) obtained acknowledgement from the DOC (who have written to a number of other countries requesting the formalization of further third-party traffic arrangements); (d) secured further privileges for K calls on VHF and above bands, and (e) received acceptance from the DOC for an increase in the frequency of examinations for AOCP, AOLCP, and AONCP. It has been a very busy and successful time!

Membership and Services

- Despite a consistent number of amateurs entering the Service, membership numbers have actually shown a slight percentage decline. The reason for this is not really known, but we can assume that the 1982/3 economic policy has been a large contributing factor.
- Traditionally, we seem to lose about 10 percent of our members at the start of the new financial year. However, as has been the case over previous years, the membership numbers always seem to increase around the middle part of the year. A large portion of those members are, in fact, renewals from the past year.
- At the time of writing this report, however, the renewals are about 15 percent down from the trends for previous years. This is a serious situation, and it requires constant monitoring by the Divisions and Executive Office.
- We must come to grips with communication to our members, particularly the outlying ones.

TOO MANY REQUESTS

I, like other correspondents to "*73* International," am receiving many letters due to the great interest in this section of *73*. I have received up to 10 letters per week with requests for information and, with the upsurge in interest in Australia by Americans, most requests are for Australiana-type information, both past and present.

In the words of that immortal song, "I am only a common old working man—and when I get a couple of drinks on a Saturday..." Unfortunately, "working man" means 6 days per week and does not leave much time for chasing up information or requests, let alone those drinks on a Saturday night, and a lot of my drinking money goes on postage because up until now only one out of ten writers bothered to send an SASE. [*Ed. note to correspondents: Try to remember always to enclose IRCs for return postage with request letters sent abroad.*]

Trying to alleviate this problem and satisfy what is apparently a great demand for this type of information on Australia, I will, in the future, if an area I am writing about is of particular historical or present-day interest, try to satisfy the needs of those amateurs who don't have big beams or linears and cannot glean this information for themselves via the medium of amateur radio. Also, I will put a greater emphasis on background information than on some of the more mundane amateur-radio information in that area.

Amyr Khan Klink PY2KAQ at the launching of the Paraty.

LONE BRAZILIAN HAM CROSSES THE ATLANTIC

Having left Luderitz City, Namibia, on the southwest coast of Africa on June 10, 1984, the 28-year-old Brazilian ham Amyr Khan Klink PY2KAQ is trying to cross the Atlantic Ocean alone in his 6-meter rowboat!

Not just any mad adventure, it is a long-planned scientific expedition sponsored by the Brazilian IAT-Companhia de Comercio Exterior (Exterior Trading Company), and was studied to its smallest details. Under the supervision of French radio-navigation specialist Maurice Uguen, who was the same to Willy Roos' "North Western Passage" to the Arctics, to Janusz Kurbiel and his polar expedition, and to the *Williwaw* on its next round-the-pole trip to Antarctica, this fantastic journey is raising tremendous worldwide interest.

An economist and President-Director to Paraty Investments, S.A., Amyr is an amateur skipper and navigator for high-sea races, a rower for the Esperia Club in Sao Paulo, did Hobie Cat 16 crossings from Paraty to Santos City in 1979 and from Salvador City to Santos in 1980, has sailed from Salvador to Fernando de Noronha Islands and to French Guiana in 1982 for Atlantic Ocean currents studies, and has canoed from Paraty to Ilha Grande Island and from Santos to Paraty.

This first-time-chosen route, 7000 kilometers long and requiring an estimated three months to cover, allowed for the Benguela, South Equatorial, and Brazil Currents between South Africa and the Brazilian coast—and also the southeastern winds, all aiming at Salvador City in Brazil.

The specially-constructed six-meter rowboat has food and water supplies for a five-month journey. Built of laminated cedar wood by late Alpha, Ltd., Shipyards in Rio de Janeiro, all plans and calculations were made by JCF Engineering, Ltd. It was taken to Ludertiz with everything on board except drinking water.

Absolutely unsinkable due to sealed compartments full of special plastic foam, highly resistant to shocks, with sun-power panels for battery charging, and a complete amateur-radio station aboard for communications, the rowboat, the *Paraty*, has two sealed cockpits and will always be upright. Even if strong waves or wind turns it over, liquid ballast placed under the waterline will right it.

Painted "rescue-yellow" above the waterline with metal radar-reflecting belts, it is painted under water with anti-fouling green and marine blue to avoid ce-

taceous attention. Batteries power the HF and VHF communications equipment, lights, navigation, and radar-detecting rigs.

A dehydrated-food program was supplied by Nutrimetal, S.A., under the supervision of technician Flora Lys Spolidoro, with 3800 calories per day being settled on as ideal; vitamins and mineral salts were included. Weekly consumption packages (seven daily-use packages in each) were numbered and subdivided for correct mealtimes so as to discipline meal consumption. Thirty days of extra food was provided for safety.

Physicians and a rowing technician took care of Amyr's physical preparation, check-ups, and evaluations at the Paciornick Hospital. Constant radio contacts with Dr. Edison Mantovani Barbosa, who was responsible for the pharmacy aboard, would provide all the support needed through PY2ARS, Alvaro's amateur-radio station in Sao Paulo.

Alvaro's antenna factory (ARS Electronica Industrial, S.A.) prepared the collapsible HF antenna for 15 and 20 meters with quick-change traps; HF equipment is a Kenwood TS-130; VHF equipment is a Brazilian Control, S.A., HT-type transceiver, 5 channels, and 0.1 or 2.2 Watts output, internal rechargeable battery; two extra battery chargers were supplied, too. Three VHF antennas, one fixed at the cockpit, a second telescoping antenna, and a Heliflex antenna provide this mode.

Together with the 275-liter-capacity tanks for drinking water, a rain-holding device at the cockpit, and two inflatable sun distillers, there was an experimental chemical salt-eliminator using an ion-exchange system (from the US Air Force).

As of now, Amyr has already traveled more than half the way. He keeps in touch with five Brazilian and French stations for weather predictions, information, and family news.

Any problem can be attended to through a parallel system of all equipment aboard. Each piece of equipment is numbered on a control map, so spare parts, repair materials, chemical compounds, medicines, or anything else for any emergency can easily be located. Instructions can be radioed to Amyr, with CW used as an extra backup.

Hand and buttock blisters were the first problems faced by Amyr after days of rowing, but Dr. Edison's attendance quickly stopped them.

Storms with seven- or eight-meter-high waves, sharks, and whales are "part of the show," Amyr says when QSOing.

During good weather, his daily routine includes some 8 or 10 hours of rowing, some rest each two hours, a close-to-8-hour sleeping period inside the cockpit, and the other hours on jobs like navigation, maintenance, radio skeds, kitchen affairs, and so on. During bad weather, when no rowing is possible, boat controlling from inside the sealed cockpit is the job, and a one-week-provisions package is provided in this place in case the second cockpit is too hard to reach.

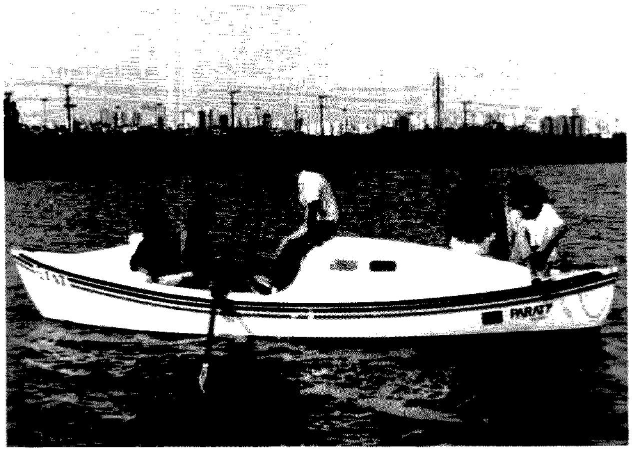
Daily jobs are all preplanned and must be carefully executed. Some jobs may become quite exciting, like removing coatings and small sea animals from the bottom of the boat—which slow the boat speed and, what's worse, attract fishes and then sharks to eat them. Swimming in the middle of the Atlantic Ocean is not a very pleasant idea, and sharks scratching the boat make for a rather uncomfortable sensation, Amyr says.

Considering the probable 109-day calculated duration of the journey, and having left Luderitz June 10, Amyr will have reached Salvador City in early October, and although the *Paraty* has already turned over some four or five times, everything is perfectly under control and going according to Maurice Uguen's predictions. The sealed-boat project approved by Maurice is the main cause for this successful expedition, and according to his analysis, Gerard D'Aboville's crossing from Cape Cod to Brest in 1980 and also Tom McLean's crossing, Newfoundland-Ireland in 1969, were also successful due to this fundamental point.

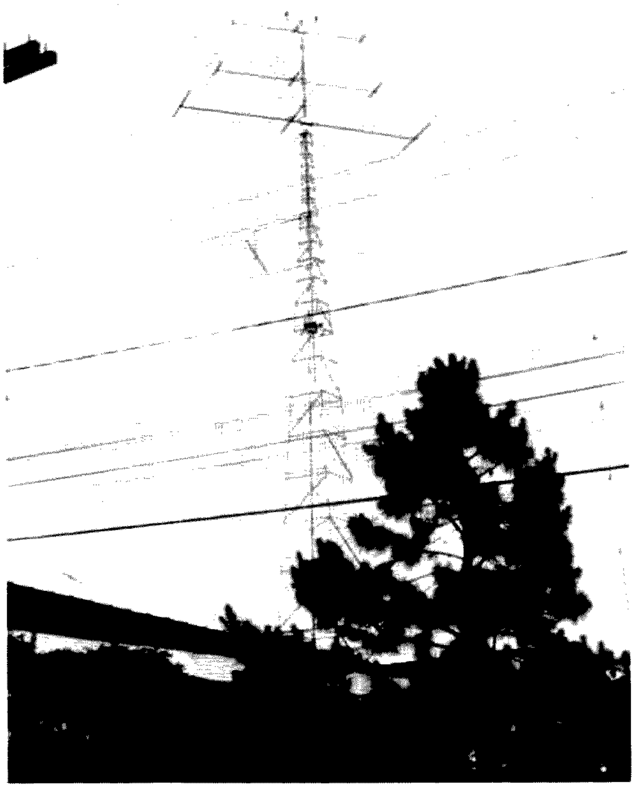
The *Paraty*'s arrival in Salvador will be just a question of time, and contacts through Brazilian Merchant Marine School's amateur station, PY1EMM in Rio, prove the efficiency of the organizer's team, so we're anxiously waiting for October's news, to celebrate this marvelous conquest of the Atlantic Ocean by our Amyr Khan Klink PY2KAQ!

Coordination of promotion data is under the supervision of Editeve Comunicacoes Ltd., in Sao Paulo.

August 30, 1984, note: Just got news Amyr is 1800 kilometers from the Brazilian coast at Bahia, and maybe he'll finish close to 20/30 September.



Amyr and friends getting the feel of Paraty*'s maneuverability. In the background is Sao Paulo City.*



The Christmas-tree beam antennas of Alvaro PY2ARS make QSOs with Amyr an easy and comfortable job.

CZECHOSLOVAKIA

Rudolf Karaba (OK3KFO ARC)
Komenskeho 1477
955 01 Topolcany
Czechoslovakia

CRC, PO Box 68, 113 27 Praha 1, Czechoslovakia, is giving these awards to non-European countries:

• *ZMT* (countries of the peace camp) This is given for contacts with stations in 39 regions according to the following list, irrespective of the bands or modes. The application should be sent to CRC with five IRCs.

OK1	UB	UP	YU
OK2	UC	UQ	YU
OK3	UD	UR	YU
HA	UF	Y	
LZ	UG	Y	
UA1	UH	Y	
UA2	UI	SP	
UA3	UJ	SP	
UA4	UL	SP	
UA6	UM	YO	
UA9	UN1	YO	
UAØ	UO	YO	

Districts in Y, SP, YO, and YU are differentiated by the last letter in the callsign. Three different numbers in the callsign are required.

All contacts since April 26, 1948, are valid.

• *ZMT 24* The same conditions as the diploma ZMT, but the contacts must be within a 24-hour period.

I have received several letters from the readers of *73* wishing to know about the structure and division of amateur radio's activity in Czechoslovakia.

The license can be obtained by every citizen of Czechoslovakia free of charge if he or she proves to have very good knowledge in operating as well as in technical activity. Or it can be also obtained by a foreign national asking for a license who is a license-holder in his own country. Following prefixes: OK, OL are used for radio hams.

OL is a private class for youths aged 15 to 19. They are permitted to broadcast on the 160-meter band on CW, with input 15 Watts, and on all UHF/VHF bands, CW/SSB also with input 15 Watts. Division of prefixes: OL1 to 7 Bohemia (Moravia); OL8 to Ø Slovakia.

OKs are divided into 4 classes: Class D can work only on the UHF/VHF bands on mode SSB/CW with input 40 Watts. It is not necessary for them to know telegraphy. This class is especially for equipment design engineers.

Class C enables one to work on the UHF/VHF bands on mode CW/SSB and also on shortwave bands in the range of 1750-1950 kHz (CW), 3520-3600 kHz (CW), and 28,100-28,200 kHz (CW). Knowledge of telegraphy *is* necessary.

Class B can work on all bands, on shortwave bands as well as on VHF/UHF, operating all modes with input 150 Watts.

Class A (Extra class) can work on all bands with input 500 Watts by all modes.

Division of prefixes: OK1—Bohemia (Czechoslovakia), OK2—Moravia, OK3—Slovakia, OK4—stations working on ships (sea/rivers), OK5 to 7—special stations, OK8—foreign nationals, OK9—special stations, OKØ—repeaters; OK1 to 3 are prefixes of general use.

Radio clubs can be operated by all holders of private callsigns as well as by operators without any private callsigns in the same classes as they were appointed (class A, B, C, D). These can work only in

radio clubs. Class C can be operated by operators who are older than 10 years. They are radio amateur transmitters. Besides that there are hundreds of technical clubs and groups of various technical interests. All the grants concerning accessories and TCVR are free of charge for radio clubs.

GREAT BRITAIN

Jeff Maynard G4EJA
10 Churchfields
Widnes WA8 9RP
Cheshire
England

After an absence of some eighteen months, I have just visited the United States again. This time I notched up my first visit to New York—and found most of the stories of the heat and humidity to be true (thank goodness for air conditioning). Unfortunately, from the tourist's viewpoint, I spent only twelve hours on the ground thanks to the Concorde.

I left London's Heathrow Airport at 1030 and arrived at JFK at 0930 for a full day's work. That same evening I departed JFK on British Airways' overnight 747 back to London. Not a great deal to do with amateur radio you might think—but I did manage to listen to a 2-meter scanner for about 15 minutes and heard something of the frenetic activity in that part of the world.

I had thought of trying to call in on a ham store before heading for JFK, but I realized that prices would no longer be competitive. When I bought my squeeze keyer and Bearcat scanner, the pound was worth $2.40—it is now worth barely half of that amount (around $1.30). It is probably cheaper to buy ham gear in the UK now for US tourists rather than vice versa.

I suppose most readers heard the Los Angeles Olympic Station, NG84O, sometime during the Games. I thought I would like a QSL from that particular station and noted the proposed operational periods of 1600 through 0400 GMT on all bands. That, of course, was a convenient time for European contacts, covering, as it does, the evening hours. However, despite several sessions listening just inside the US phone-band edges, I was unable to make any contact. Conditions do not seem to have been too good on the few occasions recently when I have ventured into the shack. I think I have mentioned previously that summer evenings and weekends tend to be reserved for playing golf. Most of my amateur-radio activity takes place in the winter (not because it's too cold for golf, but because it is too dark!).

Incidentally, you may like to know that a special UK Olympics station was planned to operate from the John F. Kennedy Memorial at Runneymede, near London. I did not listen for this station and do not know if it operated. But any readers with GK0JFK in the log not only worked it but have collected a good one for WPX! QSLs are via G3VIE (do you remember the first special station from Runneymede—WG3JFK?—I never did get my QSL confirmed!).

A glance at the recent issue of *Radio Communication*, the Radio Society of Great Britain's monthly journal, shows a continuing interest in the establishment of special-event stations. Some 15 to 20 such stations are established every month for a few days, each usually coincident with a particular public event or show.

Typical of these events are the Yeovil Festival of Transport (with the station GB2YFT), the Oldham Summer Show (GB2OSS), the Pontadrawe Folk Festival (GB4PFF), and the Pen-y-Fal Hospital Fete (GB2PYF). You will note that all of these special-event stations use GB prefixes—an ideal contribution to the WPX hunter. GB8 prefixes are also available for special-event stations, but operation is then limited to 144 MHz and above (making them an even greater catch for the US OSCAR operator).

The relatively long lead times involved in the preparation of these articles and subsequent publication in *73* preclude me from providing you with dates for special-event stations. However, I can give two dates for any reader planning trips to the UK. The RSGB Annual General Meeting will take place on the 8th of December at the IEE, Savoy Place, London. The RSGB National Convention (and exhibition) is planned for April 13-14, 1985, at the National Exhibition Center, Birmingham. Further details on either event can be obtained from the RSGB at Alma House, Cranbourne Road, Potters Bar, Herts. EN6 3JW, England.

The 1984 RSGB National Convention was again accompanied by the RSGB National HF Convention, which consisted of a series of lectures/discussions on a variety of topics throughout the day. I am much encouraged by reports that the most popular session (during which there was standing room only) was the Home Constructors Forum. This included lectures on PC-board production, test equipment, and construction techniques and was followed by a panel question-and-answer session. Let's hope for a return to home-brew gear rather than black-box purchasing as the norm.

Other topics covered during the convention included DXpeditions (including slides of trips to QJ0, VP8, ZB2, 9L, and OY), amplifiers, and general HF matters. The latter session was chaired by the RSGB's HF Manager, G3FKM, and included other well-known HF exponents on the panel. A good deal of the limited time available was spent discussing the merits or otherwise of the Society's decision not to allow trophy winners to take home their silverware for the coming twelve months!

ISRAEL

Ron Gang 4Z4MK
Kibbutz Urim
Negev Mobile Post Office 85530

THIRD-PARTY TRAFFIC IN ISRAEL

For radio amateurs in North America, traffic handling is an essential part of the hobby. Indeed, in the US our hobby is known as the Amateur Radio *Service* for this reason. In other countries, where amateur radio is licensed by the same authorities who are responsible for the postal and telephone services, third-party traffic is unheard-of or severely restricted.

In Israel, we are somewhat more fortunate than many of our counterparts in the world. A number of years ago, Mark ZL1BMU stayed at our kibbutz for a few months and was delighted to run many phone patches to the States for members of our community. This task, often routine and rather a chore at times for us here, was a pleasure for him, as phone patching was forbidden in his home country.

Israelis have many relatives living abroad, and often for them amateur radio means a link with them. Thus, for many people here, the message-handling capabilities of ham radio serves as the *raison d'etre* of our hobby. More than one disgruntled neighbor coming to complain about the lines on his television screen, after having received a communication from his cousin overseas, has returned home with a smile on his face—having completely forgotten the TVI.

To date, Israel has third-party-traffic agreements with the following countries: United States, Canada, Great Britain, Austria, Costa Rica, Panama, Switzerland, and Luxembourg. I hope there will be more official agreements and more non-hams will come to better appreciate what we have to offer.

Phone patching, legally speaking, is actually a bit more complicated. According to the licensing regulations of the Ministry of Communications, only the holders of class-A tickets are allowed to let unlicensed persons operate their stations under their direct supervision. Thus, the Ministry says that only this highest-class licensee can let a non-ham speak over his station, and only class-A amateurs may install a phone patch. To further complicate matters, he may not install any old patch, but must have the device approved by the Ministry and pay an additional licensing fee, which is considerably more than the cost of his station license.

Nevertheless, there *are* 4X/4Z stations with phone patches, although relatively speaking they are few. Roughly, only 15% of Israeli hams hold the coveted grade-A license (that allows also the use of high power), and then only a fraction of these have a patch authorization.

In fact, it isn't much of a problem to find stations in North and South America who are willing to patch us through to telephone lines on their side. For many hams this has become routine and there are various nets and skeds that take care of the traffic handling.

The problem begins when stations abroad look for Israeli hams who can run a patch for them. As mentioned above, there are relatively few hams here possessing patches, and since they are scarce and the demand greatly exceeds the supply, they do not—how shall I say it—advertise themselves. A number of years ago, the Ministry of Communications was petitioned to allow grade-B licensees to connect phone patches, but to our dismay the Ministry refused to give in.

One other difficulty, it may be added, is the peculiarity of the Israeli telephone system, which is one of the most expensive in the world to subscribe to. There is no possibility of originating collect calls, so the amateur must dial at his own expense. He does partially get around this by explaining to the party on the other end of the line as briefly as possible what's going on and having him call him back.

When the war in Lebanon broke out in the summer of 1982, the wider Israeli public came to know what an asset amateur radio is to the country. With the outbreak of hostilities, thousands of army reservists suddenly found themselves called up from their civilian roles and in Lebanon with the advancing forces. Those of them who were hams had the presence of mind to pack their two-meter hand-held rigs, and it turned out that with the rapid pace of events, they were the only means through which their fellow soldiers could notify their anxious families that they were alright.

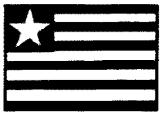
Other gear was put into action on forty-meter SSB, and along with the two northern two-meter repeaters, the airwaves were buzzing with messages day and night. In due time, the Army Communications Corps established means by which the troops could telephone out, happily putting the overworked hams out of business.

The Israel Amateur Radio Club received letters of appreciation from various units of the Israel Defense Forces, and for a while the media was full of stories dealing with amateur radio. Avi 4Z4AB, who handled over a thousand messages, was interviewed daily for a week on one of the local radio stations.

After all this, it was hoped that the Ministry of Communications would relax their regulations on the use of phone patches. No such luck. The only consolation was that none of those allegedly breaking the phone-patching regulations during that period were prosecuted.

There's an interesting side note to this, having nothing to do with the subject of phone patching. An Israeli amateur drafted into the IDF for the war noticed in one town in Lebanon a tribander on one of the houses. He knocked on the door, introduced himself as a ham, and had a very nice visit with the OD5 amateur who, for obvious reasons, will have to remain anonymous. Before leaving, he gave him his address in Tel Aviv and told him he was welcome anytime.

Imagine our friend's surprise when one evening, upon answering his doorbell, he found the Lebanese ham accompanied by two soldiers who had brought him. Many amateurs were invited over that night to meet the guest, and the next day his host took him for a tour of Tel Aviv and Jerusalem. Peace and harmony do not yet prevail completely in our region, unfortunately, but this story shows that amateur radio can form a bridge between people even under difficult times.



LIBERIA

Brother Donard Steffes, C.S.C.

PO Box 1005
Monrovia
Republic of Liberia

AMATEUR RADIO IN LIBERIA

I am off the air, and for an amateur this is a sad situation.

There was an incessant tropical rain. There was no air moving and there was no sign of electrical activity in the atmosphere. This situation is quite normal in these parts during the rainy season. The rain just starts and stops—and sometimes it doesn't stop, at least so it seems.

I turned on the 40-meter rig for a scheduled contact with one of the mission stations up country. We said hello and gave each other a signal report. Then I said, "It's raining cats and dogs in Monrovia. Let's get this job done and pull the plug." Well, we did not finish and I did not need to pull the plug. I heard a distant rumble of thunder and my radio went dead. It was a power surge.

These things do happen, and I have been told that here in Liberia these power surges will, momentarily, take the voltage in a 120-volt line to over two hundred. That is bad, but the damaging effect of the surge is compounded by the fact that it is preceded by a dip in voltage that may be well over fifty percent.

When there is electrical activity in the atmosphere in the vicinity, power surges are normal in any electrical-power distribution system. Ac electrical power is a wave phenomenon and, as such, is subject to all the laws of wave motion. Sound waves, water waves, light waves, and any other kind of waves superimpose and add algebraically. Electrical waves do the same, and the results are known as power surges. There is no electrical system that is immune. In countries that have the necessary resources, the community power system has built into it protective circuits which, in case of a severe power surge, open the circuit, shunt off the surge, and reestablish contact. During electrical storms, these momentary power interruptions are common.

Well, in this part of Africa, the power company is still trying to extend its lines to neighboring towns. They are working on the basics and there is no protection for the consumer. After an electrical storm we routinely change light bulbs that are blown.

Amateurs, of course, understand all this and many of them prefer to operate their radios on battery power, using the ac only for charging the battery. This is an effective way to protect a radio from line surges, but when you solve one problem, others arise, and in the last analysis one has to make a choice. There are advantages and disadvantages both ways.

In any case, my radio was in the transmit mode, operating at full power (100 W) when the surge came through the power line. This has to be the period when the circuit is most vulnerable. The radio itself, a TS-120S, was not damaged. The power supply in use at the time, the Astron VS-35M, was showing an output voltage of zero. I checked the four rectifying diodes. They checked out OK. Sparing you all the details, we (I and some other amateurs) concluded that the IC unit was burned out. It is not available here. We studied the circuit and made a list of parts which might need replacement. A kind American amateur whom I have never met in person is gathering these parts and will mail them by air. I would like to write his call letters for everyone to read, but in a sense so doing would be a disservice to all the other amateurs. Amateurs help each other and help others. Since I have been in Africa, I have learned more than ever the truth of that statement. I have thought many times that it would be well to write an article, "The American Amateur Seen From the Outside," or some such title. Probably it would be trite and redundant—maybe not.

However that may be, thanks again to the good American amateur, my TS-120S will be back on the air in a couple of weeks. For my part, I have learned another lesson. The book says, "Unplug the radio when not in use." In the future I will not plug in my radio during one of these tropical squalls.

HAM HELP

About three years ago I built a CMOS digital thermometer out of *Popular Science* magazine. The probe uses a Texas Instruments 6.8k Tm-1/4 sensistor with a positive temperature coefficient. I haven't been able to find this part—can anyone help?

David Shoaf WD4CZW
Rt. 5 Box 375
Mocksville NC 27028

Just a note to some of the readers concerning "Ham Help." If someone sends you the information you need, please send an acknowledgement back to that person, perhaps including the postage. After all, he or she went out of the way to find and copy the material for you.

I don't know how many people respond to these requests for help, but in April I mailed 78 pages of information to 7 different hams. Only one person, a teacher, returned a note of thanks. In January it was 5 sets of information—with no replies.

I'll still send the stuff out, but I wonder what happened to the spirit of amateur radio?

NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

This month I thought I would try to give *73* readers a brief summary of the economic position in New Zealand at the basic level and relate that to amateur radio. All figures are in New Zealand dollars (which are equal to about $US0.48 each).

The average basic weekly wage for a qualified tradesperson is somewhere in the region of about $210/220 per week, or $10,920/11,440 per year. The tax rate for this group of New Zealanders is 31.5 cents on the dollar, or between $65.10 and $68.20 per week, reducing the take-home pay to $144.90/151.80 per week.

Land tax on real estate owned is somewhere between $500 and $1000 per year, depending on the location of the property. Indirect taxation in the form of a government sales tax is added to about 50% of the goods we consume, and this sales tax is in the region of 20–30% of the wholesale price of the goods. Another comparative price is that of petrol (gasoline), the ZL motorists paying $4.00 per gallon for premium grade (or $0.89 per liter as we buy our gas since going metric).

Those of us interested in amateur radio are amongst the most affected when the cost of our radio equipment is compared to that of some overseas countries, the customs duty and sales tax being an additional burden hams have to put up with to follow our hobby. For instance, an antenna-tuning unit produced by MFJ, retailing in the US at $US139.95, sells retail in ZL for $NZ459.00. (The direct conversion of the US price to New Zealand currency is about $NZ291.00, the difference being made up by customs duty and sales tax.)

The New Zealand prices for a sampling of amateur equipment are as follows:

IC-02A	$450.00 (approx.)
IC-751	$2280 (approx.) with built-in power supply and desk mike
Yaesu FT-One	$4648 complete
TET HB33SP	$598.00

So, as readers can see from the sampling above, there is a difference when comparisons are made, but don't let this mislead you, amateur radio is still flourishing here in ZL despite the high costs involved. There are many proud owners of high-priced rigs, as the survey mentioned later in this column will reveal. The newcomer to amateur radio usually resorts to second-hand equipment for a start and then, when finances allow, graduates to a more modern new or near-new rig which is proudly described in QSOs or eyeballs at club rooms.

BITS 'N' PIECES

The Post Office has announced that there will be changes in the Amateur Operators Exam, effective September, 1984. Whereas previously the exam consisted of a combination of multiple-choice and short-essay-type questions plus the odd circuit to be drawn or commented on and a good knowledge of the Radio Regulations as they are written, the new-style examination will consist of 80 multiple-choice questions with only one correct answer, no circuits or essay-type answers, and the regulations portion will have more emphasis on the candidate's own explanation of the various regulations covering amateur radio. For these written parts of the A. O. Exam, a 50% pass mark is required for the Technician's grade-III license (non-Morse) and, of course, the 12-word-per-minute Morse test for the grade-II license.

Recently, NZART decided to make a membership survey to help the Council in planning for the future. The response to the survey was very gratifying, with over 89% of the survey papers being returned, and that's quite good for any type of poll. (As was expected, a few took umbrage at what they saw as an intrusion into their private business, and others were a little coy when it came to disclosing the true worth of their gear.) The following were the results in the various survey headings:

Age Distribution

Over half of our members (55.7%) are over 50 years of age, and three-quarters are over 40 (see Fig. 1).

Value of Equipment

This section was under two headings, Home-Brew and Commercial. The majority of home-brew equipment (67%) was valued at under $1000, whereas the peak (35%) for commercial equipment came at $3000. At the other end of the scale, only 1.6% of home-brew equipment was valued at $7500, and 1.4% of commercial gear was valued at $10,000 or above (see Fig. 2). Some proudly claimed all home-brew; others equally proudly, all commercial.

Planning Permission for Antennas

This section drew the fewest responses of all. Only 9.7% of those who answered this section have planning permission for their antennae.

TVI, BCI, and Other Interference

24.6% had experienced trouble in this area, and of that number just over half (53.5%) had consulted the Post Office Radio Inspectors, our regulatory controllers.

Financial Membership of a Branch

79.5% of those surveyed belong to Branches of NZART.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared postcards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I am a handicapped ham and would greatly appreciate any working equipment anyone would be willing to donate to set up a station. I have multiple sclerosis and have been taken off work so I have no money for ham equipment. Anything you send will be so greatly appreciated.

J. T. Statham KA5UKP

NEW PRODUCTS

MFJ-407 DELUXE ELECTRONIC KEYER

MFJ Enterprises, Inc., introduces the MFJ-407 Deluxe Electronic Keyer to its line of amateur-radio products. The MFJ-407 features iambic operation with squeeze-key, dot-dash insertion, and semiautomatic operation that provides automatic dots and manual dashes. The keyer also features a dot-dash memory, self-completing dots and dashes, jam-proof spacing, and instant-start keying.

Solid-state keying is provided for use with tube or solid-state transmitters. Front-panel controls include linear speed, weight, tone, and volume controls as well as on/off, tune, and semiautomatic switches.

Weight control allows you to adjust the dot-dash space ratio, thus making your signal distinctive to penetrate QRM. A tune switch keys the transmitter for tuning.

The MFJ-407 is rf-proof, has a built-in speaker, and uses a 9-volt battery (not included) or 110 V ac with an ac adapter (MFJ-1305.) The keyer comes in an attractive black aluminum cabinet with a black front plate. The unit measures 7 × 2 × 6 inches.

For more information, write *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762.* Reader Service number 480.

MFJ's electronic keyer.

MOUSER RELAYS

Mouser Electronics announces its entry into the relay market with a quality line of DIP reed relays, the ME431-2000 series. Their DIP-style packaging makes them completely compatible with in-line ICs, and the terminal patterns mate with standard 14-pin DIP sockets. They feature a stable transfer of low signal levels that minimizes interface buffering.

The relays are available in three standard contact forms—1A, 2A, and 1C. Their contacts are rated at 4 or 10 W, with switching currents of 0.3 or 0.5 A and a switching voltage of 30 or 100 V dc. They feature a minimum insulation resistance of 10^{10} Ohms and a maximum operation/release time of 1.0 ms.

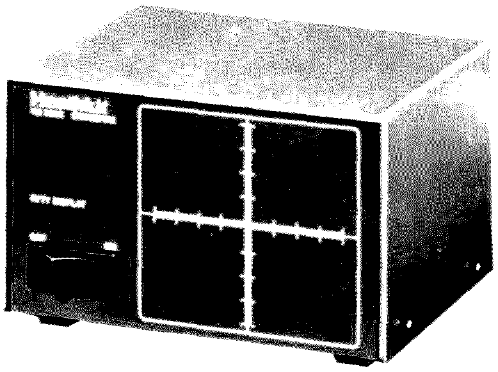
For further details and for a free catalog, write or call *Mouser Electronics, 11433 Woodside Ave., Santee CA 92076; (619)-449-2222.* Reader Service number 476.

TAU SPC-3000 ATU

TAU Systems, Ltd., has announced a new addition to their line of antenna-matching units. The SPC-3000 ATU uses an infinitely-variable roller inductor and 5-kV air-dielectric capacitors arranged in an SPC configuration. A built-in 4:1 balun, rated at 1 kW, is also included.

The front panel sports a counter for the roller inductor, a five-position antenna switch, and two meters—one monitors forward power, the other swr. The unit will

The Tau SPC-3000 ATU.



Heath's RTTY tuning aid.

operate continuously from 1.5 to 29.350 MHz, and is rated for full legal-limit power.

For further details on the SPC-3000 or TAU's complete line of parts and kits, contact *TAU Systems, Ltd., 51 Greenhey Place, East Gillibrands, Skelmersdale WN8 92A, England.* Reader Service number 482.

DIRECTION-FINDING EQUIPMENT FROM DOPPLER

Doppler Systems' latest line of radio-direction-finding units operates with any narrow-band FM receiver in the 27–500-MHz range to provide fast location of interfering signals. No receiver modifications are required—the direction finder connects to the receiver's antenna and external-speaker jacks.

Four economical models are available which provide a range of optional display and remote-output features: a 16-LED compass rose, a 3-digit bearing in degrees, an RS-232C output, and a synthesized voice output. The speech synthesizer is designed for mobile use, as it eliminates the need for the driver to watch the display.

The system operates by continuously summing the outputs of four antennas, simulating the motion of a single rotating antenna. As the simulated antenna moves toward the rf source, an increase in the apparent signal frequency occurs, and as the antenna moves away from the source, this frequency decreases. The up/down (Doppler) frequency shift is detected by the FM receiver and is present as a 300-Hz tone on the audio output. The phase of the tone is measured and used to compute the bearing without affecting the normal operation of the receiver.

For more information, contact *Doppler Systems, 5540 E. Charter Oak, Scottsdale AZ 85254; (602)-998-1151.* Reader Service number 477.

HEATHKIT RTTY TUNING AID

The new HD-3006 Crossfire Tuning indicator is a visual tuning indicator for radioteletype (RTTY) communication. Sixteen LEDs make up the display: Eight vertical LEDs identify mark signal strength while eight horizontal LEDs do the same for space signal strength. Tuning the indicator for maximum vertical and horizontal display will provide a strong signal for computers or RTTY printers. Each LED bar requires approximately 14 dB no-signal-to-signal voltage ratio for full operation. Minimum input signal is 0.3 V ac rms or 0.5 V dc. Maximum signal is 15 V ac rms or 15 V dc.

The HD-3006 has a wide voltage range and is compatible with almost any interface/terminal unit that has oscilloscope outputs for tuning. The ac/dc cube-type power supply is included in the kit.

To receive a copy of Heathkit's free catalog, write *Heath Company, Dept. 150-435, Benton Harbor MI 49022.* Reader Service number 483.

EASYTALK BY NADY

Nady Systems' EasyTalk™ personal radio communicators are ideal for outdoor activities when close contact with a partner or group is desirable. EasyTalk communicators are lightweight, rugged, and easy to operate. The units are voice-triggered so the user's hands are free. Range is up to ½ mile in optimum conditions.

EasyTalk, from Nady Systems.

EasyTalk operates in the 49-MHz FM band. No license is required for use. Model PRC-1X is a clip-on bodypack transceiver with attached headset. The PRC-1X works in the simplex mode—any number of units on the same channel can be used in an area, with users speaking one at a time. Transmission is voice-activated (VOX) or push-to-talk (PTT), with a PTT button on the bodypack. An optional remote-PTT button on a one-meter cable is available.

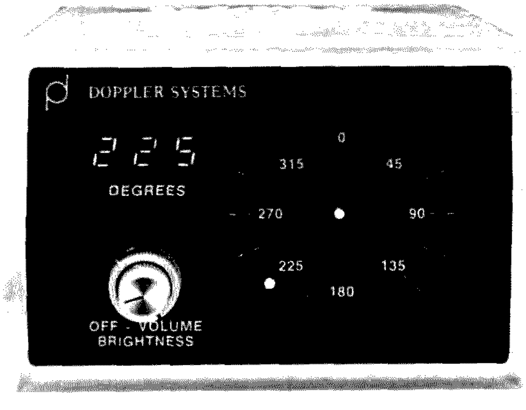
Model PRC-3X features full-duplex operation—two users can converse simultaneously, as they would on a telephone. The unit is also a clip-on bodypack with headset.

Nady EasyTalk communicators incorporate the latest advances in integrated-circuit technology. The receiver is a highly sensitive dual-conversion superheterodyne for clean, noise-free reception. Headphone volume is adjustable, and the microphone is a unidirectional, noise-cancelling type allowing voice-triggered use in high-noise environments. The microphone is mounted on a flexible boom which holds its position for individual users. Additional features include a call feature to save batteries and a flashing LED indicator to warn of low battery level.

For more information, contact *Nady Systems, Inc., 1145 65th Street, Oakland CA 94608; (415) 652-7632.* Reader Service number 481.

AMTOR-10A FROM HAL

Hal's new AMTOR-10A allows transmission and reception of radio-teleprinter sig-



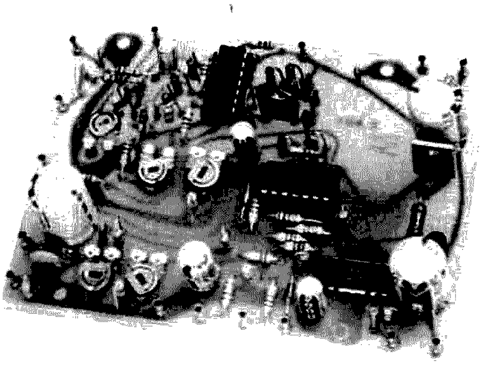
Doppler Systems' DF unit.

The Hal AMTOR-10A.

nals with the added feature of error correction. The ITU 7-unit code is used for error correction as defined by CCIR Recommendation 476-2. The AMTOR-10A is a code- and speed-converter unit that, when used with the CWR6850, allows 7-unit AMTOR code communications at 100 baud while retaining communications capability with the standard 5-unit Baudot code from 20 to 100 baud, and the 8-unit ASCII code from 75 to 200 baud. The AMTOR-10A is designed to easily interface with the CWR6850 while retaining all of the standard features of the unit, including CW capability. Modes and functions are selected from the keyboard of the CWR6850.

For additional details, write or call *Hal Communications Corp., PO Box 365, Urbana IL 61801; (217)-367-7373.* Reader Service number 479.

HAMTRONICS COR-3



The COR-3 from Hamtronics.

Hamtronics®, Inc., has announced the availability of a new version of their popular COR module, called the COR-3. Like the COR-2 module, the new COR-3 has all the circuitry needed to control a transmitter and receiver to make a repeater: an electronic relay to switch the transmitter on and off as a function of the receiver squelch, a tail timer, a time-out timer, an audio mixer, and a local-speaker amplifier. The COR-3 also has an added courtesy-beep function, including an additional timer which allows the beep delay to be adjusted to up to five seconds after the receiver squelch drops.

Whenever a station using the repeater releases his microphone, a beep tone is heard on the repeater after a short delay period. The beep indicates that the party has finished talking and the time-out timer is reset. The adjustable delay, which is in addition to the normal carrier tail, eliminates talk-over by encouraging users to wait for breakers before picking up the conversation.

For more information on this module and other transmitter, receiver, and control modules for building repeaters, or for a free copy of Hamtronics' new catalog, write to *Hamtronics, Inc., 65F Moul Road, Hilton NY 14468-9353; (716)-392-9430.* Reader Service number 478.

HANDY REFERENCE CARD FROM MICRO LOGIC

If you design or repair electronic circuits, you can now get a handy plastic reference card that lets you get right to the basic workings of everything from op amps to programmable unijunction transistors without having to go through theory, fabrication methods, or advanced terminology. From Micro Logic Corp. of Hackensack NJ, Micro-Chart #10, entitled "Active Electronic Components," is a two-sided 8-½"-by-11" plastic card that is packed with information.

Non-digital functions readily available in a single monolithic package are covered, including 13 diode types, 6 types of transistors, 5 families of thyristors, 4 types of light emitters, 9 types of light receivers, analog switches, A/D and D/A converters, comparators, multipliers, one-shots, op amps, opto-couplers, PLLs, bridge rectifiers, sample-and-hold circuits, Schmitt triggers, tone decoders, varistors, vcos, voltage followers, voltage regulators, and more. Typical descriptions cover: name of part, signal names, detailed operation, and examples of key specification parameters.

For more information, contact *Micro Logic, Dept. P, PO Box 174, Hackensack NJ 07602; (201)-342-6518.*

REVIEW

IC-37A

Those of you not active on 220 MHz over the past several years could not possibly understand. A new base/mobile rig for 1¼ meters can provoke the same excitement as working XZ on five bands. After all, there hasn't been a credible entry in the 220 base/mobile market since the Midland 13-509 and 13-513, some five years back.

All that has changed now with the introduction of the ICOM 37A. For those who don't already know about it, this rig is part of the series which includes the IC-27A and 27H, and the soon-to-be-released IC-47A. If you haven't seen one of these rigs yet, you have a surprise coming. The 37, like its brothers, is *tiny*. Also, like its brothers, it has a very hot receiver, some very nice features, and a few drawbacks. But I'm getting ahead of myself a bit.

You should know that the rig I got was a demo at Dayton, which should give you some idea of its condition. While certainly undamaged, it had been well pawed over—so I knew it would be an excellent specimen for review. Also, because of this, I got my review unit in an ICOM bag, without either a manual or a box. ICOM did send the manual later. But without the book, I had to learn how to operate the rig on my own, which was difficult. I finally found another IC-37 owner who gave me the information I needed to learn the ropes on the rig. He and several other IC-37 owners also gave me several comments which are included in this review. Don AF9M graciously supplied the use of his two-way-radio shop for the measurements used in this review. Both his 37 and mine were measured.

The very first thing I learned about this rig was its absolutely beautiful transmit audio quality. I was told, right off, that this rig runs rings around anything on the air, and having heard several 37s by now, I have to agree. However, when you get your rig, be prepared to drop by the local two-way shop or local repeater techie and have your deviation checked. Both my rig and AF9M's had the modulation cranked up too high. Both the mike gain and deviation potentiometer could stand minor adjustment. Also, have you PL™ deviation checked—it may be too low. The sine wave coming out of the PL generator is so pure that, without any harmonics of any kind, the typical PL detector will be somewhat at a loss as to what to do with it. Really! As supplied, the PL deviation is set for 500 Hz. 750 Hz will do the job much better.

The receive audio is not quite as pretty, but let's be fair about this. The rig is tiny (remember?) and there is simply no room in there for a luxury speaker. In a home listening environment, the internal speaker is very adequate. In the relatively high ambient noise level of an automobile, a better speaker is a *must*. Enough said.

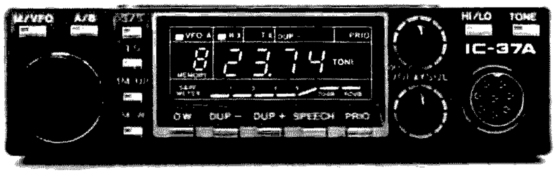
Receive sensitivity is no problem, and no additional preamp is needed. It specs out at .20 μV/m for 12 dB Sinad. Be careful when making Sinad measurements. Although nobody else had this problem, the audio stage of my rig went into oscillation and died when we hooked the leads across the speaker. No, we didn't short anything out. My rig just didn't like test leads, that's all.

One other aspect of receiver performance worth noting is the ability to handle high-rf environments, such as in downtown urban areas. The IC-37 seems to hold its own in downtown Chicago, though we're trying more testing.

Back on the transmit side there is more good news. This rig is clean, clean, clean. All of the IC-37s which were tested checked out at 80 dB down for spurs and 75 dB down for harmonics. White noise (checked on my rig only) was down 65 dB from the carrier output 50 kHz either side of the carrier. Yes, the rig could almost be used in repeater service.

I said, "almost." I found only two complaints from users about the IC-37, and the big one is *heat*. The case gets beastly hot during transmit, sometimes too hot to touch. Now I know that there have been no failures in any IC-37A to date which could be traced to heat, so I know that ICOM seems to have done their homework in the thermal-design department. But I'm from the school which says, "too hot to touch is too hot," and this still scares me a lot. Two thoughts on this: First, both high *and* low power are adjustable. Yes, the rig is rated at 25 honest Watts and yes, it will honestly put out those Watts. But if you're a bit squeamish about heat like I am, you may want to back down the high-power output to, say, 18 or 20 Watts and get yourself some insurance against heat failure. Second, it is mandatory to make sure that: a) the rig is well ventilated, and b) the cover is buttoned-down tight on the rig if you're going to transmit with it. ICOM has designed the 37's mechanical structure so that the entire case is a heat sink, and it needs all of it.

While we're still in the gripe department, there is a problem with the offset system in the IC-37A. The rig, as supplied, is programmed for an automatic −1.6-MHz offset in the repeat mode, unless you change it. So far, so good. However, if you wish to change to another offset, you can only program offbeat offsets in 100-kHz increments. The fact that you can't do it in 10-kHz increments is a real



The IC-37A 220-MHz transceiver from ICOM.

WHAT DO YOU THINK?

Have you recently purchased a new product that has been reviewed in *73*? If you have, write and tell us what *you* think about it. *73* will publish your comments so you can share them with other hams, as part of our continuing effort to bring you the best in new product information and reviews. Send your thoughts to Review Editor, *73: Amateur Radio's Technical Journal*, Peterborough NH 03458.

problem, and I would strongly suggest that ICOM change the software in their controller to allow 10-kHz-offset adjustment increments. That's it on the complaints.

The instruction manual is the typical well-done ICOM book. What more can I say? The schematic is clean and well laid-out. All rig adjustments are well documented, and the text is very straightforward.

There is, at this time, one option available with the rig, a speech synthesizer. When this option is in place and the speech button is pushed, the frequency on the display (receive or transmit) is spoken through the speaker by a synthesized female voice. I am not sure I would take this option, although it may be useful in the car when I have to watch the road and not the rig. However, for the sightless ham, this is the only way to go. The $30 price is more than worth it.

The PL generator (standard) is right on the money, frequency-wise, though as mentioned earlier, it is a little on the low side, deviation-wise. In the memory modes, the correct PL is automatically keyed in on those frequencies where you need it. However, it only works in the duplex mode, not on simplex.

Other nice features include up/down switches on the mike to help prevent auto accidents when you're tuning the rig, two vfos, and three modes of scanning: memory, band segment, or the entire band. I find the scanning rate a little slow in the memory mode and would suggest that the fast/slow scan switch (a DIP switch inside the rig) be left on fast at all times. Other nice touches: fuses on *both* the positive and the negative supply leads. If something goes wrong in your car's electrical system, you'll thank ICOM for their forethought. The mobile mount is well designed, rugged, and functional. And finally, there is provision for an outboard battery for the memory in the power plug.

A lot more could be written about this rig, and probably will be in the months to come. It would suffice to say, however, that with everything taken into account, the IC-37A was well worth waiting for. It may not be too farfetched to suggest that this may be the next standard rig for 220 FM. The IC-37A is priced at about $450 (without synthesizer option).

For further information, contact *ICOM America, Inc., 2112-116th Ave. NE, Bellevue WA 98004; (206)-454-8155.* Reader Service number 484.

IC-37A

	Spec	Measured
Power requirements	13.8 volts	
high power	6.5 Amps	6.2 Amps
low power	3.0 Amps	2.4 Amps
receive	0.5 Amps	
Rf output	25 Watts	23.5-25.5 Watts (adjustable)
Rf output/input impedance	50 Ohms	
Receiver sensitivity	0.2 μV/m, 12 dB Sinad	0.2 μV/m, 12 dB Sinad
Maximum frequency deviation	± 5 kHz	± 6 kHz
Spurious emissions	60 dB below carrier	65 dB, white noise 75 dB, harmonics 80 dB, others

NCG 7-21-50

If you didn't know to begin with, you probably wouldn't be able to tell that this little transceiver is a QRP rig. On-the-air reports are very satisfying, with praise for good audio and clean CW keying. The receiver compares very favorably with others I've used, particularly with respect to recovered audio. It's crystal clear and plenty loud when you want it to be.

What I'm talking about is NCG's newest import from Japan—a neat, small, three-band quality package that sells for $445. The 7-21-50 seems to fill a gap between the full-house transceivers that cost an arm and a leg and those which offer only CW or a single band.

If you're wondering about coverage, you get 300 kHz on 40 meters, 450 kHz on 15 meters, and 500 kHz on 6 meters! That's right—*six meters.* As you may have guessed, these three bands are permitted in Japan for the Class-B (ten-Watt) group of operators who build their skills (considerable, at that) while using low power. Don't sneeze at ten Watts, however, because it's enough for worldwide communications under favorable band conditions. In a little over an hour of part-time operating, I've been able to work Arizona on 15-meter phone, New Mexico on 15 CW, Kansas on 40 CW, and Virginia, South Carolina, and Tennessee on 40 phone. Nope, I haven't worked any six-meter stations yet, but I haven't heard any either—in spite of considerable listening. Peterborough, New Hampshire is not exactly the hub of VHF activity these days, and we're just far enough from Boston (with lots of hills in between) to be unable to pick up their local 6-meter activity. During the time I have been listening on six, there hasn't been any sporadic-E propagation, either. There's no doubt in my mind that the results on six will be as favorable as those on the other two bands as soon as things "hotten up" a bit.

Circuit Features

The local-oscillator section uses a phase-locked-loop system in which the vfo output is used as one input for the phase comparator and a mixed-down vco signal is used for the other input. With this arrangement, the vco output can be used as is for the local-oscillator signal. This reduces internal beat noise during reception and minimizes production of spurious signals during transmission. The phase-comparator frequency is in the 700-kHz range, which tends to reduce adverse S/N-ratio effects sometimes found with normal PLL systems. The transceiver's frequency stability is exactly the same as that of the vfo, which can be quite good through the use of temperature compensation and the fact that it is a low frequency (in the 3-MHz range) to begin with.

The NCG 7-21-50.

NCG 7-21-50

Size
9-3/4" × 4-3/8" × 11-3/4"
11 pounds
Frequency Range
40 meters—7.0-7.3 MHz
15 meters—21.0-21.45 MHz
6 meters—50.0-50.50 MHz
Mode
SSB—lower on 40-meter band, upper on 15- and 6-meter bands
CW—all bands
Stability
From one minute to sixty minutes after switch-on, within ± 1 kHz. Thereafter, within 100 Hz per thirty minutes
Power (Input/Output)
26 Watts PEP input
10 Watts PEP output
Power Supply
ac—120 V, 60 Hz
dc—13.8 V ± 10% (negative ground)
Antenna Impedance
50 Ohms, nominal unbalanced coax
Suppression
SSB—50 dB or more (1.5-kHz modulating frequency)
Carrier—40 dB or more
Spurious—40 dB or more (40 and 15 meters); 60 dB or more (6 meters)
Receiver
Single conversion superheterodyne using a 9-MHz i-f on SSB and an 8.9993-MHz i-f on CW
Sensitivity
Better than 0.25 microvolts for a 10-dB S/N
Selectivity
SSB: − 6 dB ± 1.1 kHz, − 60 dB ± 3 kHz maximum
CW: − 6 dB ± 200 Hz, − 60 dB ± 3 kHz maximum
Image Ratio
Greater than 60 dB
I-f Rejection
60 dB or greater
Other Spurious
70 dB or greater
Delta F (Incremental Tuning) Range
± 1.5 kHz
Audio Output Power
Internal speaker—0.5 W at 10% distortion at 8 Ohms nominal
External speaker—1.5 W at 10% distortion at 8 Ohms nominal

In the receiver section, switching between lower sideband and upper sideband is automatically accomplished when the bandswitch is changed, ensuring that the proper sideband is always in use no matter which band is in use. A 9-MHz monolithic filter removes unwanted nearby signals from the i-f frequency, which is then amplified and product detected in the usual manner by the 3-stage i-f amplifier. For SSB, the detected af signal is sent to the audio amplifier, but for CW, it first passes through an op-amp active filter for improved selectivity.

The noise blanker employs an IC to amplify mixer output noise, which is then rectified and dc amplified before being applied to the i-f on/off gating circuit.

The transmitter uses the filter-type SSB generation scheme, with an i-f frequency of 9 MHz, in a single-conversion circuit. Voice signals are amplified by low-noise transistors and presented to a balanced-modulator IC, which produces a DSB signal without a carrier. The DSB signal passes through a monolithic filter which removes the carrier, resulting in the desired SSB signal. The desired SSB signal is amplified by i-f amplifier and then frequency converted by a double-balanced mixer to the desired output frequency. An LC bandpass filter removes spurious signals from the mixer's rf output signal, which is then amplified to the 10-W output level by a 7-50-MHz wideband amplifier. The wideband amplifier features a push-pull configuration in all three stages (preamplification, driver, and final amplifier), reducing distortion and canceling even harmonics. The amplified 10-W signal then passes through low-pass filters for each band to remove harmonic components, and is then presented to the rf output connector. A portion of the drive power is rectified in a negative-feedback circuit and presented to the input gate of the FET i-f amplifier, reducing its gain and causing the ALC indicator's LED to light.

It is recommended that the antenna vswr not exceed 1.5:1 without the use of an antenna tuner. It is also suggested that continuous CW output be limited to no more than 3 minutes. For RTTY or SSTV use, the microphone gain control should be turned down to reduce the rf output to about 50% or less of the rated output (to avoid excessive heat and damage to the final solid-state power amplifiers). The operator is cautioned never to change the bandswitch while transmitting or operate the transmitter without an antenna connected to the output terminal—otherwise the power-amplifier transistor will be damaged.

Conclusion

The first (very slight) reservation I have about this neat little rig is the fact that only the "normal" sideband is provided for each band, which effectively prevents one from receiving or transmitting on the "opposite" sideband. This is something that I rarely do, anyway, so the loss is negligible with regard to my operating habits. The other reservation I have is about the ultra-fast tuning. By that I mean the large

frequency excursion with each rotation of the tuning dial. Fortunately, the dial is fairly firm, and a careful touch can be developed to tune in a station without too much trouble. Also, the built-in fine-tuning arrangement, using the "delta F" controls, simplifies matters greatly. If you tend to be a frequency hopper, you will like the fast tuning which permits you to jump from low to high end of any band in a few quick turns of the knob.

Otherwise, I can't really fault any aspect of this little rig. . .not even the 10-Watt output. It would be very easy to provide a nice solid-state external linear amplifier that could give the output of a more usual station transceiver. For the low price you pay compared to other rigs, you won't be getting all of the bells and whistles, but you will be getting a really good CW filter, good audio reports, and a go-anywhere transceiver suitable for portable/mobile QRP operation on either 12 volts dc or 110 volts ac. You don't have to buy any kind of external power supply and you don't have to buy a microphone. You will need only a key of your favorite type and an antenna. Portability, simplicity, digital frequency readout, light weight, small size, a built-in speaker, and many other things you'll like are standard equipment with the NCG 7-21-50. Of course, you didn't expect big-rig performance, and I won't kid you into thinking that you'll get it every time. . .but you will be happily surprised at the reports you do get, and even happier with the price.

BELDEN 9913 COAX

Ordinarily, the introduction of a new type of coaxial cable would not merit a write-up in an amateur-radio journal. However, Belden's new type 9913 RG-8/U cable is such a radical departure from previous RG-8/U-type cables that it does indeed merit such attention—not only from its intended market, the new 800-MHz cellular-radio service, but from amateur VHF/UHF enthusiasts as well.

What makes 9913 different from other conventional RG-8/U coaxial cables is its construction: Belden uses a single, solid #10 copper wire for the center conductor, then encases it in a polyfoam-type dielectric. The difference is that only a small, spiral-shaped portion of the dielectric actually rests against the center conductor. The balance of the dielectric immediately surrounding the center conductor is—you guessed it—air. And air makes an excellent dielectric at VHF/UHF frequencies, which would indicate good low-loss performance from 50 MHz through 1000 MHz.

The shield is clever, too: A thin film of solid aluminum foil is durabonded to the dielectric to provide 100% shield coverage. Wound around this is about 60%-coverage tinned wire to facilitate solder connections. The final cover is the black UV-resistant poly jacket. All this in a cable that has the same outside dimensions as conventional RG-8/U cables! The best description of 9913 would be a cross between hardline and CATV-type RG-59/U coaxial cable.

As might be expected, 9913 is not a truly flexible line. It could best be described as semi-rigid coaxial cable, as opposed to rigid-aluminum or corrugated-jacket cable. Yet, the minimum bend radius is specified at 8 inches. Try that with a piece of 1/2" hardline sometime! 9913 will fit all standard coax fittings for RG-8/U cables, such as UHF and N connectors (requiring some modifications on the latter).

Tests were performed by the members of SCORE (Society of Contest Operators and Radio Experimenters) to determine the actual loss an average amateur might see in normal use. Tests were made using nothing more than high-power rf sources on each band and two Bird Model 43 wattmeters at each end. Additionally, a Bird Termaline coaxial resistor was connected at the end to present a constant 50-Ohm impedance to the source through 1 GHz. We swept an entire 1000-foot put-up on every band except 1296 MHz, where the unavailability of high-power equipment resulted in our testing only a 100-foot piece of cable. All tests were done using type-N connectors throughout.

Results are shown in Fig. 1, and they are very good indeed. 9913 holds its own against most conventional transmission lines through about 30 MHz (including Belden's other non-standard RG-8/U, type 8214), but there is a dramatic difference above this frequency. Consider that most conventional RG-8/U cables have over 2.5 dB loss at 144 MHz, while 9913 comes in almost 1 full dB lower. Not only that, a figure of 2.7 dB per 100 feet at 432 MHz for a soft transmission line such as RG-8/U is outstanding. Most other cables will exhibit a loss anywhere from 3.5-5 dB at this frequency!

Clearly, this cable was designed with the 800-MHz cellular user in mind. The lucky hams who have been able to obtain lengths of 9913 (the factory has it constantly back-ordered) have put it to a myriad of uses. Several are even using it as feedlines for antennas at up to 1296 MHz. Two amateurs in Florida are claiming a QRP DX record on 1296 MHz using 350 microwatts through about 100 feet of 9913 to loop yagis. The distance worked was over 320 miles! Some simple math will tell you that only about half the power made it to the antenna—a pretty impressive record, in any event. Try that with conventional RG-8 and the loss will be about 8-10 dB per 100 feet.

Here at KT2B I use 9913 for 65-foot-long transmission lines at 144 MHz and for pigtails on 432 and 1296 from 1/2" hardline. The loss at 144 MHz compares favorably with 1/2" hardline and the loss at 1296 is only about 2 dB worse than Prodelin 1/2" Spir-O-Line cable, which uses a similar spiral dielectric. 9913 works exceptionally well at HF as a high-power coaxial line. The large center conductor can handle many Amps of rf current and the dielectric will not break down as easily as regular RG-8/U. Our group, SCORE, is currently testing 9913 for use as coaxial-balun material on 20- and 15-meter beams.

Now—about using coaxial connectors. If you prefer PL-259/UHF-type connectors, you will find the installation the same as with regular RG-8/U cable. The #10 center conductor makes a snug fit into the center pin. The braid, however, is somewhat tricky to secure. I suggest tinning the braid lightly with a soldering iron of no more than 40 Watts rating. Do not use a 100/150-Watt gun, as you run a risk of melting or distorting the dielectric! This will ruin the performance of the cable and likely cause a severe impedance bump at the joint. If you lightly tin the braid, then it will be easy to solder through the solder holes on the plug and finish the connection. Again, use a low-wattage iron. Don't try to remove the aluminum foil from the center dielectric when you pull the braid back either. At 50 MHz, 144 MHz, and 220 MHz, it is a very good idea to use PL-259s with a Teflon™ dielectric. Amphenol makes these and several radio distributors sell them for about $2.00 each.

Type-N connectors are another story. Since this is a relatively new cable, it'll take some time before the major connector manufacturers come out with a 50-Ohm type-N plug that will accommodate the #10 center conductor. Until then, you'll have to do as I did and file down the center pin until it is about #12 in diameter. It is frustrating, but the results are worth it. Additionally, you should try to use connectors that employ both a front-washer contact (between the braid and shell) and a back washer (between the rear nut and rear rubber gasket). Otherwise, you are likely to pull the connector off the first time you twist it! 9913 depends on its foil for shielding and the braid is not substantial, so a friction fit with conventional type-N connectors may be undependable. Kings Mfg. Co. makes a line of type-N connectors that employ both back and front washers and I recommend these highly. Failing that, you can use regular type-N connectors if you install a front washer yourself. Without it, you'll have a loose connection!

In summary, Belden 9913 makes an excellent all-purpose flexible line with some of the characteristics of hardline. It is an outstanding performer at VHF and UHF, and is the answer for those using crank-up towers with VHF/UHF arrays on them. 9913 is available through dealers for about 43¢-48¢ per foot, in 100-foot lengths.

For more information, write *Belden Corp., Elec. Div., Dept. G, PO Box 1980, Richmond IN 47374.* Reader Service number 486.

USING THE AO-10 APOGEE PREDICTIONS

Apogee predictions for the month of December are provided for three sections of the United States: Washington DC at 39N 77W, Kansas at 39N 95W, and California at 38N 122W. Times are in UTC and apogee in this case is mean anomaly 128 rounded to the nearest whole hour. Use the chart as a guide in aiming your antenna, then fine-tune the azimuth and elevation values to peak the satellite's beacon signal. If you require more accurate orbital predictions, contact AMSAT at PO Box 27, Washington DC 20044.

SPECIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received by 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine St., Peterborough NH 03458.

BULLHEAD CITY AZ
NOV-DEC

Bullhead City, Arizona and the Western Arizona Radio Club will join forces to celebrate an historic occasion. Bullhead City, a well established community on the Colorado River, became incorporated in late August and is now the newest city in the state of Arizona. In honor of this occasion, during the months of November and December, any station working a member of the Western Arizona Radio Club will be offered an attractive certificate. All amateur bands will be operated, including 2 meters. A QSL and an SASE (6.5" × 9") will be required (include two extra 20-cent stamps for a bonus information package). Address your request to WARC, PO Box 416, Bullhead City AZ 86430.

FARIBAULT MN
DEC 1

The annual Handi-Ham Winter Hamfest will be held on Saturday, December 1, 1984, at the Eagles Club in Faribault MN. Registration will begin at 9:00 am. There will be a Handi-Ham equipment auction, a program, and dinner at noon. Talk-in on .19/.79. For more information, contact Don Franz WØFIT, 1114 Frank Avenue, Albert Lea MN 56007.

SANTA CLAUS IN
DEC 1-2

The Pike County Amateur Radio Club of Winslow IN will operate station W9CZH beginning at 1700Z, December 1, 1984, until 1700Z, December 2, 1984. The approximate frequencies will be 3.925, 7.265, 14.265, and 21.395 phone, 7.133 CW, and 146.52 FM. A special QSL/Xmas card postmarked from the Santa Claus Post Office will be sent upon receipt of an SASE to W9CZH, RR 1, Box 311, Winslow IN 47598.

EVERGLADES NATIONAL PARK
DEC 1-2

The Everglades ARC will operate special-event station W4SVI on December 1 and 2, 1984, to commemorate the 37th anniversary of the dedication of the Everglades National Park. W4SVI will operate from Flamingo on the southern tip of Florida between 1300Z and 2300Z both days. Frequencies: lower edge of the 10-to-40-meter General phone bands as well as 146.52 FM. Certificate for large SASE to Everglades ARC, 14511 SW 287 Street, Leisure City FL 33033. Enclose your QSL card for display at the Miami Hamboree in February.

BETHLEHEM PA
DEC 21-23

The Delaware-Lehigh Amateur Radio Club (W3OK) in conjunction with the Christmas City, Bethlehem PA, will operate December 21-23, 1984, from 1500Z to 0200Z, on frequencies 3990 kHz, 7299 kHz, 14.225 kHz, 21.325 kHz, and 28.525 kHz. For a certificate of contact, send a large SASE to DLARC W3OK, Greystone Building, Gracedale, Nazareth PA 18064.

SOUTH BEND IN
JAN 6

A hamfest swap and shop will be held on Sunday, January 6, 1985, at the Century Center, downtown on US 33 Oneway North between the St. Joseph Bank Building and the river, South Bend IN. Open tables are $1.00 per foot in a carpeted half-acre room. The Industrial History Museum is in the same building. Four-lane highways lead to the site from all directions. Talk-in on .52/.52, .99/.39, .93/.33, .78/.18, .69/.09, and 145.29. For more information, contact Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 46616, or phone (219)-233-3507.

WEST ALLIS WI
JAN 12

The West Allis Radio Amateur Club will sponsor the "Original" Annual Midwinter Swapfest on Saturday, January 12, 1985, beginning at 8:00 am, at the Waukesha County Expo Center Forum (take I-94 to Co. F, south to FT, west to Expo). Admission is $2.00 in advance and $3.00 at the door. Four-foot tables are $3.00 in advance (December 31st deadline) and $4.00 at the door. Food will be available. For

tickets, send an SASE to WARAC Swapfest, PO Box 1072, Milwaukee WI 53201.

RICHMOND VA
JAN 13

The Richmond Amateur Telecommunications Society will sponsor the eighth annual Richmond Frostfest on Sunday, January 13, 1985, from 8:30 am to 3:30 pm, at the Virginia State Fairgrounds. General admission is $4.00. Flea-market spaces are $3.00 without a table and $7.00 with an 8-foot table. Booths with side curtains and backdrops are available to dealers and exhibitors and the building will be open Saturday afternoon for setup (there will be armed security at all times). The entire show will be indoors with no outside tailgating. The deadline for booths is December 30, 1984, and for the flea market January 10, 1985. For more information, write Richmond Frostfest, PO Box 1070, Richmond VA 23208, or call Bill Scruggs N4DDM at (804)-272-8206.

SOUTHFIELD MI
JAN 20

The Southfield High School Amateur Radio Club will sponsor its 20th annual Swap and Shop on January 20, 1985, from 8:00 am to 3:00 pm, at Southfield High School, 24675 Lahser, Southfield MI. Admission is $2.50. Two 8-foot reserved tables are $20.00 and each addtional reserved table is $10.00 (paid in advance). Tables will be available at the door. Doors will open at 6:00 am for exhibitors. There will be plenty of parking and food. All profits go toward electronics scholarships and to support the activities of the Southfield High School Amateur Radio Club. For more information, advance tickets, and/or reservations, write Mr. Robert Younker, Southfield High School, 24675 Lahser, Southfield MI 48034. Indicate with your reservation whether you will need wall space and/or electrical outlets. All table reservations will be confirmed.

YONKERS NY
JAN 27

The Yonkers Amateur Radio Club will sponsor the Yonkers Electronics Auction on Sunday, January 27, 1985, from 9:00 am to 3:00 pm, at Lemko Hall, 556 Yonkers Avenue, Yonkers NY. Admission for buyers and sellers is $3.00 each; children under 8 will be admitted free. New and used equipment will be auctioned and can be inspected from 9:00 am to 10:00 am. There will be plenty of seats and parking and the auction will start at 10:00 am sharp. Unlimited free coffee will be available all day. The club will charge a 10% commission on the first $100 and 5% on the remainder on successful sales only. Talk-in on 146.265T/146.865R, 440.150T/445.150R, and .52 direct. For more information, write YARC, 53 Hayward Street, Yonkers NY 10704, or phone (914)-969-1053.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

ARRL 160-METER CONTEST
Starts: 2200 UTC December 1
Ends: 1600 UTC December 2

The object is for amateurs worldwide to exchange QSO information with W/VE amateurs on 1.8 MHz, CW only. DX-to-DX QSOs are not permitted for contest credit. Operating categories include single-operator and multi-operator (single transmitter only). Remember that W/VE stations may transmit only in the 1800–1825- and 1830–1850-kHz segments, in conformance with the ARRL band plan. Please refrain from using the 1825–1830-kHz DX window.

EXCHANGE:

RST and ARRL section, DXCC country name, or ITU region (if maritime or aeronautical mobile).

SCORING:

Count 2 points per QSO with amateurs in an ARRL section. W/VE stations count 5 points for DX QSOs. Multiply QSO points by the total number of ARRL sections (74 max.) and DXCC countries (W/VE stations only).

ENTRIES:

Official forms and logs are recommended and are available from ARRL headquarters for an SASE or 2 IRCs. Logs must indicate time in UTC, call, and exchange. Multipliers should be clearly marked in the log the first time worked. Entries with more than 200 QSOs must include cross-check sheets. Entries must be postmarked by January 4 and sent to the ARRL, 225 Main St., Newington CT 06111.

Certificates will be awarded to the top-scoring single operator in each ARRL section and DXCC country, and to the top-scoring multi-operator station in each ARRL division and continent. Usual ARRL conditions of entry and disqualification apply.

ARRL 10-METER CONTEST
Starts: 0000 UTC December 8
Ends: 2400 UTC December 9

Contact as many stations as possible on the 28-MHz band, using no more than 36 hours of the 48-hour contest period. Listening time counts as operating time! Entry categories include: single-operator mixed-mode (phone and CW), phone only, or CW only. Multi-operator class is for single-transmitter, mixed-mode only.

No crossmode contacts are allowed. Mixed-mode single-operator and all multi-operator stations may work stations once on CW and once on SSB. One operator may not use more than one callsign from any given location during the contest period. All entrants may transmit only one signal on the air at any given time.

EXCHANGE:

W/VE stations (including KH6/KL7) send RS(T) and state or province. DX stations send RS(T) and serial number starting with 001. Maritime and aeronautical mobile stations send RS(T) and ITU region (1, 2, 3). Novice and Technician stations sign /N or /T as appropriate.

SCORING:

Count 2 points per phone QSO, 4 points per CW QSO, and 8 points for QSOs with US Novice or Technician stations. Multiply the QSO points by the total number of US states, Canadian call areas, DXCC countries (except US and Canada), and ITU regions (maritime and aeronautical mobile only).

ENTRIES:

Official logs and entry forms are recommended and are available from ARRL headquarters for an SASE or 2 IRCs. Logs must indicate time in UTC, mode, call, and exchange for each QSO. Multipliers should be clearly marked in the log the first time worked. Entries with more than 200 QSOs must include cross-check sheets. Entries must be postmarked by January 11 and sent to the ARRL, 225 Main St., Newington CT 06111.

Certificates will be awarded to: the highest-scoring single-operator station in each category from each ARRL section and DXCC country, the top multi-operator entry in each ARRL division and each continent, and additional entries as participation warrants. Usual ARRL entry conditions and disqualification rules apply.

CANADA CONTEST
Starts: 0000 UTC December 30
Ends: 2400 UTC December 30

Sponsored by the Canadian Amateur Radio Federation (CARF), the contest is open to all amateurs and everybody works everybody. Entry classes include single-operator allband, single-operator single-band, and multi-operator allband.

Use all bands from 160 to 2 meters on CW and phone combined. All contacts with amateur stations are valid. Stations may be worked twice on each band, once on CW and once on phone. No crossmode contacts and no CW contacts in the phone bands are allowed.

EXCHANGE:

Signal report, consecutive serial number starting with 001, and province.

SCORING:

Score 10 points for each contact with Canada and 4 points for contacts with other countries. VE0 counts as Canada and one multiplier. Score 20 points for each contact with any CARF official news station using the suffix TCA or VCA. Multipliers are the number of Canadian provinces/territories worked on each band, on each mode (13 provinces/territories × 2 modes for a maximum of 52 possible multipliers per band). Contacts with stations outside Canada count for points but not multipliers.

FREQUENCIES:

1810/1840, 3525/3775, 7025/7070/7155, 14025/14150, 21025/21250, 28025/28500, 50040/50110, 144090/146520. Suggest phone on the even hours (UTC), CW on the odd hours (UTC). Since this is a Canadian-sponsored contest, remember to stay within the legal frequencies for your country!

AWARDS:

A trophy will be awarded to the highest-scoring contestant in each entry class. A certificate will be awarded for the highest score in each category in each province/territory, US call area, and DX country.

ENTRIES:

A valid entry must contain log sheets, dupe sheets or statement, a cover sheet showing claimed QSO points, a list of multipliers, and a calculation of final claimed score. Cover sheets and multiplier checklists are available. Entries should be mailed within one month of the contest, with your comments, photos, etc., to: CARF, c/o N. Waltho VE6VW, General Delivery, Morinville AB, T0G 1P0, Canada.

Results will be published in *TCA*, the Canadian amateur magazine, prior to the next contest. Nonsubscribers of CARF may include an SASE for a copy of the results. The decision of the contest committee shall be final in all cases of dispute.

G-QRP-CLUB WINTER SPORTS

Daily from 0900 to 2300 UTC, December 26 to January 1. All radio amateurs interested in QRP are invited to take part in the club's activity. No special exchange information was mentioned in the information provided by the club. The operating schedule for each day is as follow:

0900–1000 UTC	= 14060
1000–1100	= 21060/28060
1100–1200	= 7030
1200–1300	= 3560
1300–1400	= 10106
1400–1500	= 3560
1500–1730	= 21060/28060
1730–2000	= 14060
2000–2100	= 7030/10106
2100–2200	= 3560
2200–2300	= 14060

Reports on the Winter Sports Activity should be sent to Fred Garratt G4HOM, 47 Tilshead Close, Druids Heath, Birmingham B14 5LT, England.

LONG ISLAND MOBILE AMATEUR RADIO CLUB Inc.
LIMARC LOG

NEWSLETTER OF THE MONTH

Rounding out the list of winners in 1984 is the journal of the Long Island Mobile Amateur Radio Club—the *LIMARC Log*. Editor Earl Grainger W2NXZ puts together this compendium of news and views, and does it in a consistently professional manner.

There are two areas which the *LIMARC Log* has in common with previous winners: format and content. Of course, the content is first-rate; the newsletter is full of stories and tidbits that are just plain fun to read. A recurring theme among winners seems to be the use of paid advertising. When not overdone, this can provide a steady source of income for the club and will result in a high-quality publication.

On the format side, most successful newsletters are offset-printed using an 8-1/2"-by-5" size, and look like a miniature magazine. Some use colored paper to highlight news and add excitement. The extra price is worth it—a well-presented newsletter will cause your membership roster to grow quickly!

To enter your club's newsletter in *73*'s Newsletter of the Month Contest, send it to *73*, Pine Street, Peterborough NH 03458, Attn: Newsletter of the Month.

40-meter phone during the specified times of allowable operation. The same station may be worked only once. Crossmode contacts will not count. Single-operator stations may operate a total of 16 hours. All the multi-operator stations may operate the entire 24-hour period. Off periods must be noted in your log(s) and on your summary sheet. Off periods are *no less than 30 minutes each.*

OPERATOR CLASSES:

(A) single-operator, single transmitter, phone only. (B) multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the contiguous 48 US states and Canada transmit an RS report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:

5 QSO points for contacts with W/VE stations located within the continental 48 US states and Canada. All other contacts score 10 points each. List points for each contact on your log sheet.

MULTIPLIERS:

1 multiplier point is earned for each US state (48 maximum—a District of Columbia contact may be substituted for a Maryland multiplier), each Canadian province or territory (13 max.), and DX Country (excluding the contiguous US and Canada).

FINAL SCORES:

Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Each entry must include a contest log, a dupe sheet, a contest summary, and multiplier checklist. We recommend that contestants send for a copy of the contest forms. Enclose an SASE to the contest address listed below.

CONTEST DEADLINE:

Each entry must be postmarked no later than February 12, 1985.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each operator class in each of the contiguous 48 states, Canadian provinces and territories, and each DX country represented. A minimum of 100 OSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:

To obtain entry forms or submit an entry, forward an SASE to: 40-Meter Contest, Dennis Younker NE6I, 43261 Sixth Street East, Lancaster CA 93535.

G3ZRS, W3BE, AND K8EX RTTY WORLD CHAMPIONS

This year's World RTTY Championship was an absolute thriller. This was the third year of joint sponsorship by the *RTTY Journal* and *73*. Only 4400 points separated single-operator champion G3ZRS from second-place finisher SM6ASD. Throughout the contest there was only a couple-thousand-point margin between many of the contestants.

Peter Rodmell G3ZRS became world champion for single-operator stations while John Johnston W3BE and K. L. Miller VE7YB took the United States and Canadian championships, respectively.

On twenty meters, Dima Slyusarenko UT5RP took a commanding lead for this single-band championship. Piero Giacomelli IK5CKL became the fifteen-meter singles champ.

Mike Bottema K8EX tallied the highest contest score, becoming the world multi-operator champion. For single-band entries, multi-operator Sodermans Regemente SL5AR became the twenty-meter winner with 61,920 contest points.

Everyone apparently had a good time. The enthusiasm of the contestants spreads with each year's event. From the logs received, we've extracted some of the comments made.

RTTY CHAMPIONSHIP SOAPBOX

VE6BEV	This is my first contest. It sure was fun.
VE7ATH	This is my first RTTY contest. I enjoyed it very much. Sure hope conditions are better next time, though.
N7AKQ	Bands were good this weekend. Larger turnout, too! Had a great time and look forward to next year.
WA2KOK	Nice contest. Many signals from Europe.
KØTIV	My first RTTY contest. My greatest thrill was working my first DX.
SP2UUU	Just got my license in October and now all my family is QRV on RTTY. Enjoyed the contest.
VE7VP	Enjoyed the contest and picked up two new countries.
HZ1AB	All continents except Africa. Earned a few new states.
W3BE	Wonderful contest!
PA3DBS	Very nice event. It was my first. Made many nice QSOs, and the conditions were good.
K6WZ	Almost got WAC on 10 meters.
KT1N	Been on RTTY 3 months and only sorry I didn't get started 25 years sooner. Had a ball.
EA5CVR	Enjoyed it very much.
VE6ZX	Enjoyed the contest very much. Forty and eighty meters were tough.
ON7EP	Great test.
SM6ASD	Twenty and fifteen meters exceeded everything I have experienced so far in RTTY contesting. Fantastic activity! I definitely look forward to the years ahead.
WP4AVW/EA4	My very first contest.
CT1AV	Thanks for the test. I am ready for 1985!
GW3EHN	Had power failure. There's always next year—I hope.
GU6JST	Glad to activate Guernsey on RTTY.
WB3FIZ	Good DXing. Both the wife (KA3GIK) and I thoroughly enjoyed it!
K8EX	This is our second year. A good time was had by all.

As Dee Crumpton N6ELP, *RTTY Journal* editor, and her staff put it, "It was fun, a lot of work, a lot of headaches compiling the scores, but we would do it all over again, anytime."

Our special thanks to Dee and the staff! Without the *RTTY Journal* behind this RTTY classic, we are sure this third annual event would not have made it this far. It's getting bigger and better each and every year. See you all next February for the 4th Annual World RTTY Championship.

4TH ANNUAL 75-METER WORLD SSB CHAMPIONSHIP 0000Z to 2400Z January 13

SPONSORED BY:

73: Amateur Radio's Technical Journal.

MISCELLANEOUS RULES:

Work as many stations as possible on 75-meter phone during the specified times of allowable operation.The same station may be worked only once. Crossmode contacts will not count. Single-operator stations may operate a total of 16 hours. All multi-operator stations may operate the entire 24-hour period. Off periods must be noted in your log(s) and on your summary sheet. Off periods are *no less than 30 minutes each.*

OPERATOR CLASS:

(A) single-operator, single transmitter, phone only. (B) multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the contiguous 48 US states and Canada transmit an RS report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:

5 QSO points for contacts with W/VE stations located within the contiguous 48 US states and Canada. All other contacts are 10 points each. List points for each contact on your log sheets.

MULTIPLIERS:

1 multiplier point is earned for each US state (48 maximum—a District of Columbia contact may be substituted for a state of Maryland multiplier), each Canadian province or territory (13 maximum), and DX country (excluding the contiguous US and Canada).

FINAL SCORE:

Total OSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Each entry must include a contest log, a dupe sheet, a contest summary, and a multiplier checklist. We recommend contestants send for a copy of the contest forms. Enclose an SASE to the contest address listed below.

ENTRY DEADLINE:

All entries must be postmarked no later than February 13, 1985.

DISQUALIFICATIONS:

phone only. (B) multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the contiguous 48 US states and Canada transmit RS report and state or province/territory. All others transmit RS report and DX country.

POINTS:

5 QSO points for contact with W/VE stations contacted within the contiguous 48 US states and Canada. All other contacts earn 10 points each.

MULTIPLIERS:

1 multiplier point will be earned for each of the contiguous US states (48 maximum—a District of Columbia contact may be substituted for a state of Maryland multiplier), each of the Canadian provinces/territories (13 maximum), and each DX country outside the contiguous 48 US states and Canada.

FINAL SCORE:

Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Each entry must include log sheets, a dupe sheet for 100 or more contacts, a contest summary, and a multiplier check sheet.

ENTRY DEADLINE:

All entries must be postmarked no later than February 20, 1985.

DX WINDOW:

Stations are expected to observe the DX window from 1.825-1.830 MHz as mutually agreed by Top-Band operators. Stations in the US and Canada are asked not to transmit in this 5-kHz segment of the band. During the contest all W/VE stations are requested to utilize only those frequencies from 1.808-1.825 and 1.830-1.900 MHz.

DISQUALIFICATIONS:

Disqualification may result if contestants omit any required entry form, operate in excess of legal power authorized for the given area, manipulate operating times to achieve score advantage, or fail to omit duplicate contacts which would reduce the overall score more than 2%. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each entry category in each of the contiguous 48 US states, each Canadian province/territory, and each DX country. A minimum of 100 QSOs must be worked to qualify.

CONTEST ADDRESS:

To obtain information or entry forms, or to submit a contest entry, forward an SASE to: 160-Meter Contest, Harry Arsenault K1PLR, 603 Powell Avenue, Erie PA 16505.

1ST ANNUAL 15-METER WORLD SSB CHAMPIONSHIP
0000Z to 2400Z January 26

SPONSORED BY:

73: Amateur Radio's Technical Journal.

MISCELLANEOUS RULES:

Work as many stations as possible on 15-meter phone during the specified times of allowable operation. Stations may be worked once. Crossmode contacts will not count. Single-operator stations may operate a total of 16 hours. All multi-operator stations may operate the entire 24-hour period. Off periods must be noted in your logs and on your summary sheet. Off periods are *no less than 30 minutes each.*

OPERATOR CLASS:

(A) single-operator, single transmitter, phone only. (B) multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the contiguous 48 US states and Canada transmit an RS report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:

5 QSO points for contact *within* your continent. 10 QSO points for contact *outside* your continent. List points for each contact on your log sheets.

MULTIPLIERS:

1 multiplier point is earned for each US state (48 maximum—a District of Columbia contact may be substituted for a state of Maryland multiplier), each Canadian province or territory (13 maximum), and DX country (excluding the contiguous US and Canada).

FINAL SCORE:

Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Each entry must include a contest log, a dupe sheet, a contest summary, and a multiplier checklist. We recommend contestants send for a copy of the contest forms. Enclose an SASE to the contest address listed below.

ENTRY DEADLINES:

All entries must be postmarked no later than February 28, 1985.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each operator class in each of the contiguous 48 US states, Canadian provinces and territories, and each DX country represented. A minimum of 100 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:

To obtain entry forms or to submit an entry, forward an SASE to: 15-Meter Contest Chairman, Bill Gosney KE7C, 2665 N. Busby Rd., Oak Harbor WA 98277.

OPERATOR CLASSES:

(A) single-operator, single transmitter, phone only. (B) multi-operator, single transmitter, phone only.

EXCHANGE:

Stations within the 48 contiguous US states and Canada transmit an RS report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RS report and DX country.

POINTS:

5 QSO points for contact *within* your continent. 10 QSO points for contact *outside* your continent. List points for each contact on your log sheets.

MULTIPLIERS:

1 multiplier point is earned for each US state (48 maximum—a District of Columbia contact may be substituted for a Maryland multiplier), each Canadian province or territory (13 maximum), and DX country (excluding the contiguous US and Canada).

FINAL SCORES:

Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Each entry must include a contest log, a dupe sheet, a contest summary, and a multiplier checklist. We recommend that contestants send for a copy of the contest forms. Enclose an SASE to the contest address listed below.

CONTEST DEADLINE:

Each entry must be postmarked no later than February 27, 1985.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification. Decisions of the contest committee are final.

AWARDS:

Contest awards will be issued in each operator class in each of the contiguous 48 US states, Canadian provinces and territories, and each DX country represented. A minimum of 100 QSOs must be worked to be eligible for contest awards.

CONTEST ADDRESS:

To obtain entry forms, or to submit an entry, forward an SASE to: 20-Meter Contest Chairman, Chuck Ingram WA6R, 44720 N. 11th St. E, Lancaster CA 93535.

THE AWARDS PROGRAM OF *73: AMATEUR RADIO'S TECHNICAL JOURNAL*

It's hard to believe the years which have passed since our initial announcement of the now famous *73* Awards Program portfolio. Since its introduction by yours truly, KE7C, in 1979, we've seen the program grow to become one of the most popular challenges facing amateurs today!

Consisting of six domestic and five DX operating achievements, the program has captured the interest of many of our fellow amateurs, rag-chewers, DXers, and contesters alike.

How does *73* process award applications? Upon receipt of an application, each entry is carefully scrutinized for authenticity. They must be sent to the Awards Manager in the proper format (as noted in the award rules), otherwise they must be returned to the applicant.

If approved, a work sheet is prepared. A copy is sent to *73* headquarters to process your certificate. It is there that your award is given a personal touch and later mailed to your door. (A copy of the work sheet is also mailed to the applicant at the same time to acknowledge receipt of the application.)

Should an applicant feel it is necessary to follow up on an application, send your inquiry to: *73*, Award Certificate Processing Department, 80 Pine Street, Peterborough NH 03458, USA. Always enclose a stamped business-size envelope with your letter.

We hope you enjoy the challenges of the *73* Awards Program. We ask that you share it with your amateur friends.

While we hope you'll pursue these awards, we also ask that you send the Awards Manager any information you might have on other awards which have never appeared between the covers of this magazine. Our files are getting bare, and it is the input of our readers that keeps the image of this column original and creative! If your club sponsors an award, why not share it with our readers throughout the world?

Now here are the six domestic awards being sought after by award seekers throughout the world. These awards are not meant to be an overnight venture, nor were they designed to duplicate any in existence today. Each offers its own degree of difficulty and creates a sense of accomplishment in those who are happy recipients. Next month we'll feature our five DX awards.

THE Q-5 AWARD OF EXCELLENCE

If you frequent the American Novice bands, you will be pleased to learn of an award exclusively for this portion of the spectrum. This award is not meant to be an overnight accomplishment. Stations meeting the challenge of this award will be proud to display it in their shack. It depicts the excellence and superiority of their station's transmitted signal as it is heard throughout the various US call districts.

1. The Q-5 Award is available to licensed amateurs and SWL stations throughout the world!
2. To qualify, applicants must work all ten US call districts and receive no less than a Q-5 readability report. A valid RST might be 599, 579, 549, etc., while an RST of 459, 449, or 469 would not qualify.
3. To be valid, all contacts must be made operating CW on those frequencies assigned the American Novice Contacts must be made on or after January 1, 1979.
4. There are no band restrictions; applicants may request special band endorsement, however, at the time application is made
5. To apply, prepare a list of claimed contacts, logging each one in order by the US call district worked. Include the station callsign, date and time in GMT, the frequency, and most important, the RST as noted on the confirmation card.
6. *Do not* send *QSL cards!* Have your list verified by two amateurs or a notary public.
7. Award fee is $5.00 in US funds (no IRCs or foreign currency). Checks written on foreign banks must be payable in US funds.
8. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277, USA.

CENTURY CITIES AWARD

Designed as a dual worked-all-states effort, the editors of *73* present the Century Cities Award. The applicant who has earned this recognition has accomplished probably the greatest feat available in WAS award programs.

1. This award is available to licensed amateur and SWL stations throughout the world.
2. All contacts must be made on or after January 1, 1979, to be valid.
3. To qualify, the applicant must work and confirm a minimum of two cities or towns in each of the fifty (50) US states, for a total of 100.
4. To apply, prepare a list of contacts in alphabetical order by state Include the callsign, the date and time of the contact in GMT, the band, and the city. Your list would look something like the following. First line, five columns: Alabama KA4ZZZ 4/30/84 7 MHz Decatur; second line, last four columns: W4MKU 11/15/82 21 MHz Huntsville; third line, five columns: Alaska KL7MI 5/18/83 14 MHz Anchorage, and so on.
5. *Do not send QSL cards!* Have your claimed contact list verified by two amateurs or a notary public.
6. Award fee is $5.00 in US funds. Do not send IRCs or foreign currency as they are no longer acceptable. Checks written on foreign banks must be payable in US funds.
7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277, USA.

2.	K4JSI/6

SPECIALTY COMMUNICATIONS ACHIEVEMENT AWARD (CLASS A)

1. Available to licensed amateurs and SWL stations throughout the world, this award requires that all contacts be made on or after January 1, 1979.
2. Only communications via SSTV, RTTY, EME (Earth-moon-Earth), and/or OSCAR satellites will be recognized for this award. Contacts between stations on OSCAR and EME may be made using any authorized mode allowed in your country. Mixed-mode contacts are not valid.
3. To qualify, applicants must work and confirm contact with each of the 50 US states. There are no band requirements. Specific band accomplishments will be recognized, however, if requested at the time application is made.
4. To apply, the applicant must prepare a list of claimed contacts in alphabetical order by state. Include the date and time in GMT, the band and mode of operation, and a description of the equipment and antenna system used.
5. *Do not send QSL cards!* Have your list verified by two amateurs or a notary public.
6. Award fee is $5.00 in US funds only. Sorry, we cannot accept IRCs or foreign currency.
7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277, USA.

TEN-METER 10-40 AWARD

What would an awards program be without a stateside QRP incentive? Designed especially for owners of converted CB equipment, the 10-40 award is probably the roughest worked-all-states award in existence. If you don't believe it, ask those who've tried numerous times and failed!

1. This award is available to licensed amateurs and SWL stations throughout the world.

2. To be valid, all contacts must be made on the ten-meter band using only converted CB equipment or other low-power (20 Watts output or less) commercial gear. External amplifiers are prohibited. Contacts must be made on or after October 1, 1978, on AM, SSB, CW, or FM. Crossmode contacts will not count.

3. To qualify, applicants must work and confirm at least forty (40) US states.

4. To apply, list contacts made in alphabetical order by US state beginning with Alabama. Include the call of the station worked, the date and time in GMT, the mode of operation, and a brief description of the equipment and antenna system utilized to make the contacts.

5. *Do not send QSL cards*! Have your list verified by two amateurs or a notary public.

6. Award fee is $5.00 in US funds. IRCs or foreign currency are not acceptable. Checks written on foreign banks must be in US funds.

7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277, USA.

ANNUAL WORKED ALL USA AWARD

1. If you're looking for a stateside award with a challenge, this one is definitely the one. The annual Worked All USA Award is available to licensed amateurs and SWL stations throughout the world.

2. To qualify, applicants must work each of the fifty (50) US states within the same calendar year (January 1 through December 31). Annual endorsements will be awarded each subsequent year that an applicant qualifies again.

3. All valid contacts must be made on or after January 1, 1979. There is an award for single-band accomplishments on 2, 6, 10, 15, 20, 30, 40, 75, and 160 meters. A mixed-band award is also available.

4. To apply, prepare a list of claimed contacts in alphabetical order by state. List the state, the callsign of the station worked, the date and time in GMT, and the band and mode of operation.

5. *Do not send QSL cards*! Have your list of contacts verified by two amateurs or by a notary public.

6. The fee for this award is $5.00 in US funds. Annual endorsements are $2.50. We are sorry, but we can no longer accept IRCs or foreign currency. Checks written on foreign banks must be payable in US funds.

7. Forward you application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277, USA.

DISTRICT ENDURANCE AWARD

If any of our readers feel our awards are too easy, take a hard look at this award! Looks simple, huh? Don't be deceived. Try pursuing it; it will drive you right up the wall with frustration. Known as the District Endurance Award, you'll need to find yourself an accurate timepiece, as you'll have exactly sixty (60) minutes to work all ten (10) US call districts. If you surpass the time limit, you'll have to start all over again. It definitely takes some planning, perhaps even some band changing.

Oh, one last important point. All contacts must be made independent of nets, any net-type operations, and not while a contest is underway! Any takers?

1. The District Endurance Award is available to licensed amateurs and SWL stations worldwide.

2. To be valid, all contacts must be made on or after January 1, 1979. There will be no band or mode restrictions. If you are fortunate to work all contacts on a single band, however, we will be happy to recognize that feat should you mention it at the time application is made.

3. To qualify, applicants must work all ten (10) US call districts in one hour or less. The time will commence the moment the first contact is established (callsign and RST are exchanged) and end the moment the 10th call-district contact is made. Call districts can be worked in any order so long as all ten districts are worked within the 60-minute period.

4. To apply, applicants must state in their applications that all contacts were made independent of net or contest operation. Applicants must prepare a list of claimed contacts in callsign order by district. Include the date and time in GMT, the band and mode of operation, and the state.

5. *Do not send QSL cards*! Have your claimed list of contacts verified by two amateurs or a notary public.

6. Award fee is $5.00 and must be payable in US funds (no IRCs or foreign currency). Checks written on foreign banks must be payable in US funds.

7. Forward your application and award fee to: Bill Gosney KE7C, *73* Awards Manager, 2665 N. Busby Road, Oak Harbor WA 98277, USA.

from page 60

Activity—Band Usage

On the HF bands, 40, 20, 15, and 10 meters, an average of 40% were active; 160m attracted 7%, and the new 30m band just under 5%. (This band has been available for only about 12-18 months.) At VHF and above, 4.4% operated on 6m, just over half (51%) are active on 2m, 6.4% on 70cm, and an average of 0.3% on all other bands above 70cm. Good intentions were always indicated by an average of 15% for future HF activity (presumably by way of upgrading), 11% moving up to 70cm, and 2% indicated future use of frequencies above 432 MHz.

Time Spent on Hobby

"Gilding the lily" should have been included in this section because the time the average radio operator spent at the hobby was 48.4 hours per week! No wonder some XYLs and possibly a few OMs growl now and then. The average figures given are in Fig. 3.

A rewording of the question in this section is necessary, as it is known that all individual amateurs do not participate in all these activities in any one given week, but it still is an interesting result when viewed with circumspection.

How Introduced to Amateur Radio

Personal contact with friends or relatives accounted for over 63% of the introductions to amateur radio. Just under 21% came via shortwave listening, and only 7% resulted from Branch/club activity, which was on a par with those who first read about the hobby.

How Long Before Ambition to Become an Amateur was Realized

In the age group up to 40 years it took, on average, just over a year to get a license after being infected by personal contact with another amateur at school, at work, or within the family. At the other end of the age scale, first exposure to amateur radio came through the armed forces or personal contact, and it took another seven years to get a license.

Conclusions

There is a lot to be learned from the survey, not the least being the way the questions are phrased. Figures are also required about satellite operations, packet radio, use of computers in amateur radio, and so on. Several surveys will be necessary before trends can be seen properly, but at least the completion of this, the first one, is a start to help with the planning for the future of amateur radio here in ZL.

VHF ACTIVITY FROM NIUE ISLAND

Six-meter beacon—ZK2SIX—52.100 MHz—antenna at present, an 800' long rhombic at 80' high, but it is only temporary. . . another antenna is to be built that will be a bit more omnidirectional and can be attached permanently to the beacon. The beacon was put up by Bob Sutton ZK2RS, and he reports the life of the beacon is uncertain after his departure from the island in November or December this year when he returns to ZL.

Warrick ZL8AFH, Raoul Island, finished his tour of duty there and left the island late in August. His replacement is not an amateur licensee, so once again Raoul Island goes QRT for an indefinite period.

DX QSL TIP

Ron K6OZL, who recently operated from Northern Cooks as ZK1XL, reports: When sending QSL cards to areas where it is hot and humid, put a piece of waxed paper under the flap of the self-addressed envelope you send. Out of 2500 cards he received, 2495 were stuck shut by the humidity! The other five had waxed paper under the flap.

OLD TIMERS CLUB

This is the ZL equivalent of the Quarter Century Wireless Association. Certificates were awarded to Jack Ashford ZL2RO, Graham Goodger ZL2RP, Lou Smith ZL4BF, and Bill Turner ZL1PY recently for their long association with amateur radio.

Silent keys recorded this month were Len Chisholm ZL3UK, Pat Senior ZL3VQ, and Roger Bacon ZL1SG, all long-serving amateurs and members of the OTC.

As this column, by my calculations, will appear in the December issue of *73*, I wish to thank all those who have written to me regarding the ZL scene and extend to all *73* readers and staff the best of festive greetings from all here down under in ZL-land and a very Happy Christmas. I hope Father Christmas brings you all something good for the shack on Christmas morning; I'll be thinking of you all on that special day.

NORWAY

Bjorn-Hugo Ark LA5YJ
N-3120 Andebu
Norway

Well, hi there, fellows, hope you enjoyed my last column, because here I am again, this time with a newcomer in the Norwegian amateur-radio meetings. The Skumsjoe Treff-84, the first of what I sincerely hope will be an annual meeting, because this was something new.

Only a week after our hasty return from HAM-84 in southern Germany, described in November's *73*, we had the opportunity and great pleasure to attend another ham meeting, held in the central part of Norway. Up in the mountains, it was close to an idyllic lake, the Skumsjoe Lake, surrounded by some low hills between the two cities of Raufoss and Gjoevik. Because of lack of time and some unfortunate bad weather which hit the whole area *except* this specific spot, not too many did attend, but with the results being as they were, I'm sure the number next year will be quite another story.

I must say that such a cozy meeting will never be forgotten. The program was arranged so as to get as many as possible of the hams to bring their families with them and just enjoy themselves. The ham-radio shop, Norsk Radio Supply, showed up on very short notice with an exhibition of the latest from Yaesu Musen, Telex Hy-Gain, Cushcraft, etc., and the more than 50 amateurs there had a super time seeing and touching the newest technology in ham radio. Normally, they have to travel from 2-4 hours to get to Oslo, where the shop is situated. The arrangement was made by the local section of NRRL, the Gjovik group, and one of the main goals was to get as many as possible of the local CB clubs to attend and introduce them to ham radio; I understand this was a total success and guess that we are going to get quite a few new hams from that area in the future.

Saturday night had the big feature, with a barbeque with a whole pig being roasted, dancing to music produced live by Wilfred LA6SL, amateurs chatting, wives and kids doing more or less the same, except for the few Vikings taking a bath in 14-degree-Celsius water—the author absolutely *not* included! But mind you, the pig was delicious. Knut LA9YF (maybe our new president) was attending on behalf of the HQ of NRRL and gave an informative speech to the CBers.

On Sunday there was a fox-hunting competition, with quite a few newcomers; to be honest, most of us were, including myself, and I did hear the foxes but I never saw one.

DX

My last column didn't give you any information on DX since I haven't been active at all for over a month. This is just due to too much work and traveling. Another thing is that I have moved my QTH and I can assure you that my new QTH absolutely is not the DXers dream. Later I will

give you a description of my old setup and, of course, the new one. I must say that I'm more curious than desperate about how I will manage to work any new ones at all, because those mountains will surely be a challenge to work DX over. In the meantime, you must be satisfied with reading my presentations on other DXers, who have the opportunity to work them all.

Bjorn Waller SM6EHY

One of the well-known low-band DXers in Scandinavia is Bjorn Waller SM6EHY of Hindas, Sweden. He has been one of those you always hear working the rare ones, either on 80 or 160 meters; the latter seems to be of most interest to him recently.

I had the opportunity to run into Bjorn at HAM-84 at Friedrichshafen, and it was an unforgettable moment. You may ask, why? Well, it's very seldom you are able to meet someone with such identical interests as yourself. Antennas, propagation, and low-band DXing. It's one of the rare times you always will remember. And a new friendship has been made. We had, of course, met on the air, but I think we were chatting for two hours each of the two days I was there.

Bjorn is a nice looking fellow, born in 1956 and first licensed in 1971. He's unmarried and lives with his parents in a nice villa, 35 km east of Goteborg in southern Sweden, facing a large lake. He got interested in DXing when someone told him about the possibility of working it on 80 meters, in the winter of 1976, and since then he's been really bitten by the bug. His recent DXCC status is 138 mixed and 132 CW, all on 80 meters. But he told me that he has 240 worked, all CW, all on 80 meters, and, believe it or not, 103 worked on CW on 160 meters. Remember, it was only last year that the Swedes got permission to work on 160 meters. His antenna on 160 is a 1/4-wave sloper up 30 meters above a large ground system with some 200-meter-long radials.

On 80 meters he runs a 4-element phased vertical beam with 400 radials, and having as much space as he has, he is running quite a few Beverage antennas stretched 3 meters above the ground. As he says, a total of some 23 km of wire. Wonder what the neighbors say? Or what about living in a bird cage? Hi! Anyway, he's a marvelous DXer on low bands, and watch out guys, he is really going to hit hard on the higher bands, as well. Up till now he has been running a dipole on 10 and 15 meters and a ground plane on 20 meters, but look at what he has going now: a 39-meter tower, rotatable, with stacked yagis, 6 over 6, on 20, 15, and 10 meters; on 40 meters, a 3-element yagi, but it's possible he will try a 2 over 2 instead. I sincerely wish him luck.

Bjorn SM6EHY is also very well known as an active 2-meter ham, working EME, tropo, sporadic E, and aurora; he is really keeping the air glowing with rf. His rig is, of course, a TR-7 and 4B-line all made by R. L. Drake Company, and he runs a homebrew linear amplifier giving the legal power. And if this is not enough, he is even a high-speed CW operator as well. So I really wonder, this does not sound very amateur-like. It's quite professional radioing.

Bjorn is always happy to QSO with DX; if you hear him, get yourself a schedule for an EME or low-band QSO. Where the DX is, he is. SM6EHY will surely be one of those big, big signals out of Europe, and I bet he will be hard to beat in a contest. Maybe the Finns (OHs) have some serious competition to come?

Bjorn SM6EHY at HAM-84, Friedrichshafen.

ELECTORAL CAMPAIGN

At the end of 1984, deputies to the National Congress of PRAA will gather. They were elected by district conventions, including the district convention in Katowice on March 25th, where many members and invited guests heard a lecture by the outgoing board about organization troubles related to nearly two years of licensing difficulties.

It is to be regretted that so many former hams do not put in for licenses again. The first Polish UHF-FM repeater, resumption of transmitting of district bulletins, and rapid development of the radiotelephone networks were numbered among positive aspects of district activity. The chief of the repeater group and the initiator of the Polish QRP Club gave the final lecture.

A 10-person District Board, 6-person Auditing Committee, and 22 delegates to the National Congress were elected during the convention. New President SP9MM, new Vice-President SP9EU, and continuing Secretary SP9DL entered on their duties.

Before and during the convention an equipment exchange enabled many radio amateurs to purchase components and, for the first time, circuit boards for the locally-designed transceiver, "Bartek." On April 1st the district conventions of PRAA in Poznan and Bielsko Biala took place.

Discussed at the convention in Katowice was the first Polish UHF-FM repeater in Podzamcze, near Zawiercie, built by radio amateurs of the Clubs: SP9PDG in Dabrowa Gornicza, SP9PEZ in Katowice, SP9PPP in Bytom, and SP9PKD in Zawiercie. Chief constructors of the repeater were: Jerzy Wojciechowski SP9MCW, Jacek Ziemniak SP9CSW, and Zbigniew Sitko SP9-2841.

The automatically-controlled repeater, SR9E, works on channel R0 (input 145,000 kHz, output 145,600 kHz) with the power of the transmitter set at 1 W. Installation consists of three basic subassemblies: a receiver, a transmitter, and a control system. The control system includes the generator of the callsign SR9E and a system for repeater access controllable by the modulation tone of 1750 Hz. The device mates with two independent groundplane antennas. A third antenna is being prepared for a radio beacon that would begin its work after a granting of permission. The radio beacon SP9VHE, emitting F2 with power of 100 mW, will be installed 504 meters above sea level to guarantee long range under good conditions. There are two independent diplexers between the antennas and the converter. In the future, the architects of the contraption will install more diplexers and use a common antenna for sending and receiving.

PORTUGAL

Luiz Miguel de Sousa CT4UE
PO Box 32
S. Joao do Estoril
2765 Portugal

As mentioned before, the new rules for the ham service came into force in July, 1983. However, thanks to the helpfulness of the Secretary of Communications, a commission was formed by five hams who will collaborate in review of the rules. The nominated hams are CT1VV, CT1BH, CT1WW, CT1AL, and CT1GM. We think that in the very near future we can really announce that we have rules according to the IARU Region 1 status.

I've received some letters from hams complaining of the delay in receiving QSLs via the Bureau. Despite other things written in several publications, The Portuguese QSL Bureau is in charge of R. E. P., Rede dos Emissores Portugueses (CT1REP). So send cards this way; the Bureau staff will take care of them with great care. They do handle cards almost daily.

VISITORS IN LISBON

This year, I have been very lucky meeting hams from several parts of the globe. Last July, Larry Lemas N6CCL and Wil LU8TEA (ex-CR6IK, CT4IK) came over to Portugal for their summer holidays and we had a short talk. Wil is my ex-neighbor in Africa, more precisely in Angola. Our thanks, and keep coming to this sunny European garden.

HAMS OVER THE CLOUDS

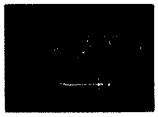
Celebrating the 32nd anniversary of the F.A.P.—Forca Aeria Portuguesa (the Portuguese Air Force) and taking an opportunity to promote this lovely hobby, two aeronautical mobile stations were active from two different airplanes. CT1CUG (Colonel Afonso), CT1GI (Lieutenant Colonel Brogueira), and CT4OA (Captain Leonel) were involved in this act. This operation had the support of the High Command, and the event was very well accepted by the hams and local authorities who issued the aeronautical mobile license. They send a nice award and QSL card for those who contacted them. The callsign used by them was CT7FAP/AM.

The planes were a Hercules C-130 and an Aviocar, and they handled the operation on their regular flights. On VHF, an ICOM 255E was used, and on HF they had a Kenwood TS-120S. These two operations were on the air for about a week, and nearly 13 flight hours were totaled. As a result, 750 contacts were made, with almost all European countries, Africa, and North and South America. For those who made contact and wish to receive a QSL card or award, you should send a QSL to: Comando Operacional da Forca Aeria, Monsanto, 1500 Lisboa, Portugal.

Last summer, I decided to go to Algarve (southern Portugal) and get some tropical weather down there. As a result, I had a nice chat with Edy G5BBD (known as the BBD of London, Hi), and I stayed 5 days with him.

Does anyone know the new address for W8CNL? If you do, drop me a line.

Finally, I do wish you a very happy and prosperous 1985, and let's look for the DXpeditions in the New Year coming.



SAUDI ARABIA

Don Muhl WA0DEI (HZ1AB)
PO Box 2445
Dhahran
Saudi Arabia

For some time now, several of us have been watching the "73 International" column in *73* for a report on Saudi Arabia. In the past several months the column has expanded to include many new countries, so several of us got together and prepared this for you. We have been quite candid and no names are listed, even those of our Saudi amateur friends, so that no one gets in trouble.

YES, AMATEUR RADIO IS ALIVE IN SAUDI ARABIA

Many amateurs worldwide have the misinformed idea, primarily from contact with the ARRL, that amateur radio doesn't exist in Saudi Arabia. This is quite far from the truth, but the curtailment of amateur radio in the Kingdom is supported by the strict rules imposed on those who do receive the right to operate. At present there are only 19 legally-licensed Saudi operators, one club station, and four non-Saudis. The last amateur-radio license was granted by the King in 1974. "Licensed" is possibly the wrong word; "decreed" would be better. There is no formal written amateur-radio license, only a letter signed by the King or one of the Royal Family Princes that allows the user to acquire equipment and then operate. Those granted such a decree then choose their own callsign in the HZ1 grouping if Saudi or in the 7Z1 grouping if non-Saudi.

Even though the Ministry of Post, Telephone, and Telecommunications (MOPTT, or PTT for short) is responsible for all radio communications, amateur operation is outside of their purview. PTT and the military only monitor the amateur operations for illegal or unauthorized usage. An example of unauthorized usage would

be to talk with any amateurs in any communist country or, especially, Israel. Even a quick exchange of signal reports is not allowed. The Saudi monitoring system is so effective that it takes less than a one-minute transmission with a 1-Watt handheld radio for the PTT to pinpoint the user to within 100 meters and send the police if it is a non-authorized user.

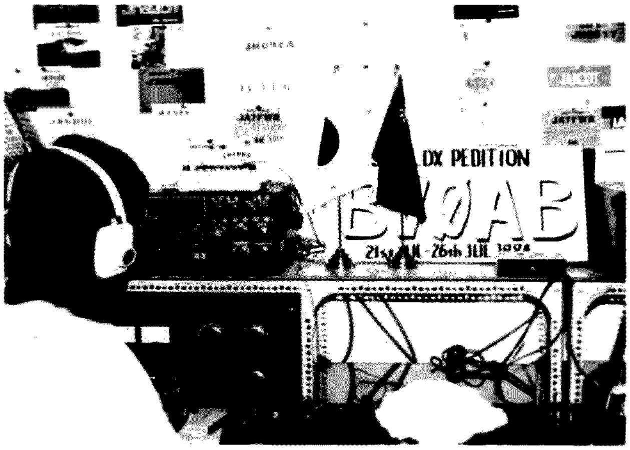
Amateur operation is limited to the five main HF bands and 2 meters; however, the 2-meter operation is limited to two channels in the 167–170-MHz range. This is specifically done so that no conversations can take place across the borders of the Kingdom with neighboring countries.

In addition to the twenty-four "licensed" operators in the Kingdom, there are also some 250 or more amateurs from other countries living and working in Saudi Arabia. Those that live and work in the Dhahran area are most fortunate, as they may visit and operate the Aramco Club Station at Dhahran Airport. This club station still operates under a Royal Decree issued by the King to Aramco prior to 1974. Any amateur-radio operator who is working in Saudi Arabia or is able through work to obtain a business visa can make arrangements through the US Army Communications Command Officer in Charge at Dhahran and may operate the club station, HZ1AB. This station, although totally under US military control, must still abide by all rules pertaining to individual amateur operators. Any slip by visitors or members operating HZ1AB could cause its shut-down immediately.

Several foreign amateurs living in Riyadh, the capital of Saudi Arabia some 400 km inland from Dhahran, attempted to establish a second club station during the summer and fall of 1983. Their efforts were totally negated thanks to two American women, a Korean, and two German businessmen who were caught within the same three-month period trying to smuggle amateur equipment into the Kingdom. This is just the tip of the iceberg when it comes to imposing restrictions on anyone, not just amateurs using HF radio. A further example is that any HF receiver capable of copying sideband is also considered a contraband item and will be confiscated by customs officials. This applies to equipment used by foreign governments as well as businesses or private citizens.

But all is not lost; many foreign amateurs do operate and quite often from the stations of those individuals who are licensed. All it takes is the nerve to get an audience with one of the licensed Princes (by the way, all licenses are to members of the Royal Family or their employees), and the Prince OKs use of his HZ callsign and operation at his station. When the four foreign employees leave, it is doubtful if any new 7Z1 callsigns will be issued until the problems in the Middle East are solved. Once one has lived in Saudi Arabia, it is easy to understand why the Saudis are very skeptical and have imposed such harsh controls over amateur-radio operations and HF radio operations in general that are not associated with their government or military.

One of the ham stations equipped by and made available by the Saudi Arabian government.



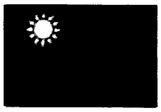
The DXpedition station, BV0AB, in Taipei, July, 1984.

One of the nice things about amateur radio in Saudi Arabia is the background of the other amateur operators one meets. For instance, the only licensed female amateur in Pakistan is with her husband working for one of the major banks; two Americans in Riyadh each hold callsigns for over 21 different countries, and there are five husband-and-wife teams. Instead of radio contacts, the hams use the several computer mailbox systems that are in existence country wide.

This pretty well covers amateur operations in Saudi Arabia. For anyone coming here to work, remember there are no tourists, and for those workers who are amateurs, remember: (1) Don't bring any equipment of any kind, including a receiver capable of sideband operation, (2) don't expect to operate just because you have a license from another country, (3) don't advertise—you can end up in jail or be deported immediately, and (4) under no condition can women be permitted to operate except at the Dhahran Club Station.

If anyone is planning employment in the Kingdom and is going to the Eastern Province (Dhahran/Al-Khobar/Damman/etc.), contact the Officer in Charge, US Army Communication Center, APO New York 09616, Attn: MARS Station, and it may save later embarrassment. For those going to the capital, Riyadh, or to any other location such as Khamis, Taif, Tabuk, or Jeddah, contact AFLC/LSG-LCC, USAF MARS Station AJ3RY, APO New York 09038 for assistance. Just remember, *don't* bring any equipment into the country. If one does receive the approval to operate, the equipment used will be that of one of the Princes at his station.

STATEMENT OF OWNERSHIP, MANAGEMENT AND CIRCULATION [illegible] John C. Burnett, Publisher



TAIWAN

Tim Chen BV2A/BV2B
PO Box 30-547
Taipei, Taiwan
Republic of China

One after another, DXpedition teams to BV-land from abroad have been coming. We're up to four now; possibly there will be two more to come in this year. Close cooperation between hams and local parties concerned show that we will have a good situation in amateur-radio activities.

The second Japanese group from JA6 was composed of the captain, JA6MS, and JA6VVS, JA6ERV, JA6GIP, JH6SOR, JE6MQW, JA5UIM/6, JF1JSP, and JH1IUN. They arrived in Taipei on July 21 and left on July 26. The trip was arranged in a hurry and their giant antennas were not received in time, so BV2A lent a 2-element tribander yagi and a 40/15-meter dipole.

Unfortunately, the weather in July was so terribly hot that the air conditioner in the operating room was of little help. Worse, radio propagation did not favor them. The callsign BV0AB was used on 7, 14, 21, and 28 MHz. Approximately 8,000 QSOs on CW and SSB were made, according to the group's statistics.

The above-mentioned late-arriving antennas consisting of a TA-351 5-element tribander yagi and a TD-3040 dipole finally arrived and were given to the CRA (China Radio Association) as a gift from the JARL. We are very appreciative of their generosity. We are also pleased to see the 2-inch callbooks of JA hams which were brought over by JA6MS and JA6VVS to a banquet given by the CRA. Mr. Chen, Division Chief of Ministry of Interiors, was asked to award a medal to both JA6MS and JA6VVS on behalf of the CRA to commemorate the special occasion and express appreciation.

Besides QSOs on the air, the Japanese were greeted by many visitors from abroad; among them were G4KLP, W9ZNY, OE3ALW, F6EXV, and JA1YDJ. Together with BV2A/BV2B, they and the representatives of the other countries talked for hours on the roof of the DXpedition station, BV0AB. Ken JA1YDJ was the captain of BV0JA and BV0YL, and he came back from Tokyo with an FT-757GX transceiver to be offered to CRA to add strength to stations in BV-land. He also brought us some copies of two popular magazines, *CQ* and *Mobil* (August issues), in which there were reports on the activities of BV0JA and BV0YL.

Although each expeditiion group did announce its QSL manager, there are still many QSL cards coming to us that we have to relay, causing considerable delay. In order to save time, here are the QSL managers: I2MQP/BV, I2NYN/BV, and I2BVS/BV via I2MQP; BV0AA via OH2BH, BV0JA and BV0YL via JG1QGT, and BV0AB via JH6SOR.

The coming expeditions (BV0W and BV0BG) will announce their QSL managers later.

As to the applications from interested DXpeditions, please be advised: apply for approval at least seven weeks ahead. It is necessary to include a detailed list of operators, licensed callsigns, the profession of each, and passport number (if available); also a list of equipment to be brought into this country stating manufacturer, model, serial number, power, frequency coverage, and numbers of transceivers or transmitters and receivers. Any omissions of the above will cause a delay in approval and call for unnecessary correspondence.

Furthermore, it is not recommended that you book your air passage before hearing from us. Owing to present facilities and limited manpower, we can allow only one expedition group in every two months. Therefore, overlapping applications will be denied or postponed. Last-minute applications can hardly be accepted.

DEALER DIRECTORY

Culver City CA

Jun's Electronics, 3919 Sepulveda Blvd., Culver City CA 90230, 390-8003. Trades 463-1886 San Diego, 827-5732 (Reno NV).

San Jose CA

Bay area's newest amateur radio store. New & used amateur radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santec & many more. Shaver Radio, Inc., 1775A S. Winchester Blvd., Campbell CA 95008, 370-6665.

Fontana CA

Complete lines ICOM, DenTron, Ten-Tec, Mirage, Cubic, Lunar, over 4000 electronic products for hobbyist, technician, experimenter. Also CB radio, landmobile. Fontana Electronics, 8628 Sierra Ave., Fontana CA 92335, 822-7710.

New Castle DE

Factory Authorized Dealer! Yaesu, ICOM, Ten-Tec, KDK, Kenwood, AEA, Kantronics, Santec. Full line of accessories. No sales tax in Delaware. One mile off I-95. Delaware Amateur Supply, 71 Meadow Road, New Castle DE 19720, 328-7728.

Preston ID

Ross WB7BYZ has the largest stock of amateur gear in the Intermountain West and the best prices. Call me for all your ham needs. Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.

Littleton MA

The reliable ham store serving NE. Full line of ICOM & Kenwood. Yaesu HTs, Drake, Daiwa, B&W accessories. Curtis & Trac keyers. Larsen, Hustler, Telex/Hy-Gain products. Mirage amps., Astron P.S., Alpha Delta protectors, ARRL & Kantronics instruction aids. Whistler radar detectors. Full line of coax fittings. TEL—COM Electronic Communications, 675 Great Rd. (Rt. 119), Littleton MA 01460, 486-3400/3040.

Livonia MI

Complete photovoltaic systems. Amateur radio, repeater, satellite, and computer applications! Call Paul WD8AHO. Encon Photovoltaics, 27600 Schoolcraft Road, Livonia MI 48150, 523-1850.

Derry NH

Serving the ham community with new and used equipment. We stock and service most major lines: AEA, Astron, Azden, B&W, Cushcraft, Hy-Gain, Hustler, ICOM, Kenwood, KLM, Larsen, Mirage, Mosley; books, rotors, cable and connectors. Business hours 9-7 Monday through Thursday, and 9-5 Friday and Saturday. Rivendell, 68 Warner Hill Road, Derry NH 03038; 434-5371.

Albany, New York UPSTATE NEW YORK

Kenwood, ICOM, Ten-Tec, Belden, Cushcraft, Larsen, Hustler, ARRL, Hy-Gain, B&W, MFJ, Mirage. New and used equipment. Serving the amateur community since 1942. Adirondack Electronics, Inc., 1991 Central Avenue, Albany NY 12205, 456-0203 (one mile west of Northway exit 2W).

Columbus OH

The biggest and best ham store in the Midwest featuring Kenwood and other quality products with working displays. We sell only the best. Authorized Kenwood service. Universal Amateur Radio, Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.

Dallas TX

IBM PC/XT kits, supplies, expansion products; video restorer kits for pay TV, CATV, satellite hobbyists' electronic project kits/appnotes. More than 9000 parts in stock: semiconductors, ICs, discretes, video accessories, tools, audio, automotive, cabinets, computer peripherals. Please write for your free 60-page catalog: Sabet Electronics, 13650 Floyd Rd., Ste. 104, Dallas TX 75243; 783-4950 (formerly I.E.).

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the March '85 issue must be in our hands by January 1st. Mail to 73 Magazine, Peterborough, NH 03458. ATTN: Nancy Ciampa.
